<sup>1</sup> Acknowledgment is made to J. C. Dort for data on the water-power resources of Alaska; to John D. Rue for data on a modified pulping process; to William N. Sparhawk for assistance in the preparation of the regional timber-stand tables; to Joseph Kittredge, jr., for the tables showing timber growth; to Robert V. Reynolds for the table showing the drain on American forests; to the Bureau of the Census for lumber cut, pulp-wood consumption, and wood-pulp production statistics for 1922; and to William B. Greeley and Herbert A. Smith for a critical review of the manuscript.

## REASONS FOR INQUIRY: ITS SCOPE.

Few, if any, of the great national problems confronting the American people are more urgent or important than that of adequate timber supplies. The products derived from our forests are so extensive and varied and contribute so vitally to national life that the entire public is concerned. Directly or indirectly the problem affects every industry regardless of the nature of its products, even those industries which produce the chief competitors of wood, such as cement and steel. Among all industries, however, the problem concerns most obviously and directly those, including pulp and paper, which manufacture their products from wood as the raw material.

For a number of reasons the problem of timber supply for pulp and paper manufacture has become more serious than it is for most wood-using industries. Relatively large plant investments make it much more difficult for paper mills to follow the retreating timber stands than is the case with lumber manufacture. Comparatively few woods have been used in paper making. These factors and the requirement, in one of the most important pulp processes, of abundant and cheap power have so far confined the production of paper to but few timber regions. Pulp manufacture in these regions has in general followed lumbering, and starting with diminished supplies of timber has reduced them still further. A stage has now been reached where many pulp and paper mills have either no timber of their own or only very limited amounts, and few have permanent supplies. Concern for future pulp-wood supplies and their relationship to the entire national forest problem led the American Paper and Pulp Association to form a special "Committee on the perpetuation of the pulp and paper industry in the United States." The committee requested the Forest Service to make an investigation, the results of which are incorporated in this report.

For the past 30 years or more the United States has imported pulp wood from Canada. For some time the volume of these imports was small; but it grew rapidly, particularly during the decade following 1900. For the past 10 years, however, pulp-wood imports have remained at substantially the same level. Fundamentally we have imported pulp wood because our own supplies of material tributary to the existing paper mills have been reduced, while our requirements for paper, pulp, and pulp wood have been expanding. The Canadian pulp and paper industry has shown a phenomenal development during the last decade, and for a number of years it has become increasingly evident that Canadian requirements will in time absorb the pulp wood which is now shipped to the United States. The fact that pulp-wood imports have been practically at a standstill for an entire decade and may now be on the brink of a decline from purely economic causes, accentuates the problem of adequate future sources of raw material which demands attention from the American pulp and paper industry and from the American public. The problem demands attention regardless of the recent action of the Canadian Parliament in giving the governor in council authority to restrict pulp-wood exports. It demands attention regardless of the recommendations which may be made by a Canadian commission now investigating the situation, or of the action which the Canadian Government finally takes. The Canadian situation, like the American, is the result of economic forces long operative and certain to continue, with important consequences for the pulp and paper industry in both countries, irrespective of their traffic in pulp wood.

Although of great importance, pulp-wood imports form only about 19 per cent of our pulp-wood consumption and about 11 per cent of the pulp wood needed to meet our entire paper requirements. During the past decade, while pulp-wood imports have been stationary, imports of both paper and pulp from

Canada and from a number of north-European countries have continued to expand. This expansion has been necessary to meet American requirements for paper. Our paper requirements have in fact grown faster than, under existing conditions, pulp wood could be obtained from our forests or paper and pulp could be produced in our mills. Our pulp and paper imports now constitute an equivalent of 42 per cent of the wood utilized in our total paper consumption, or nearly four times the imports of pulp wood alone. Even without the pulp wood they swell our imports to a greater proportional volume than in the case of any other major forest product. The exceedingly rapid growth and present volume of pulp and paper imports, in themselves alone, more than justify an inquiry into the present situation and the future outlook.

A satisfactory investigation can not therefore be confined exclusively to pulp-wood resources or to pulp-wood imports, and any emergency which might grow out of their reduction, or to paper and pulp imports. Much larger questions of trade and public policy are involved than how, if necessary, to meet a reduction of pulp-wood imports or how to keep present capital investments profitable through the discovery of domestic pulp-wood supplies. It is necessary to deal with the entire situation, with imports of paper and pulp as well as of pulp wood, and with the underlying forces which have brought about these imports. It is most necessary of all to consider just what are our present and possible future pulp-wood resources.

The scope of this investigation has therefore been planned to include:

(1) Present American pulp-wood, wood-pulp, and paper requirements, and the character and extent of our imports from Canada and other countries.

(2) Probable future paper and pulp-wood requirements.

(3) Whether we should attempt to become entirely self-supporting in the part of our paper requirements derived from wood.

(4) Existing timber resources and how we can meet from them our present raw-material requirements for the paper industry.

(5) How we can grow on our own forest lands pulp wood of satisfactory species in sufficient quantities to meet our future requirements.

(6) Supplementary measures essential to the solution of both present and future problems.

Neither time nor funds have permitted the collection of new field data. It has accordingly been possible only to compile, analyze, and interpret with especial reference to the purpose of this investigation the data already available.

## WHY WE SHOULD SEEK INDEPENDENCE IN PULP-WOOD SUPPLIES.

The question naturally arises whether we should try to meet all of our future paper requirements from domestic sources. Our economic relations with Canada are close and it is to the mutual advantage of both countries that they should so continue. Canada has a large forest area and much more timber of pulp species in her eastern Provinces than has the United States in the corresponding region. Why should not the United States acquiesce in a permanent dependence on Canada for pulp and paper to supply our densely populated Eastern States now that we have ceased to manufacture sufficient quantities from domestic timber? Why should we not also continue to secure the present or even larger amounts of pulp and paper from north-European countries?

The question turns on the economic advantages or disadvantages to the United States of the alternative courses. There are outstanding reasons for creating a permanent domestic pulp and paper industry which can meet our entire needs, founded on home-grown timber. As will be shown in a subsequent

section, no reliance can be placed upon raw materials other than wood for the great bulk of future paper supplies.

From the standpoint of national interest we obviously should not allow ourselves permanently to remain subject to the losses occasioned by the stoppage of imports of a product so essential to our national life as pulp wood. The possible stoppage of foreign pulp and paper supplies, from any one of a number of causes, would be equally objectionable to our industries, and would also work serious public hardship. In case of a permanent stoppage of such imports, the time within which they could be replaced at home becomes a factor of great importance. With domestic timber available we might enlarge our pulp and paper industry to almost any extent required within 10 years at the most, but to grow the timber needed would require from 20 years under the most favorable conditions to 40 or 50 years in some of our forest regions.

Both the quantity and the price of foreign pulp and paper are becoming increasingly dependent upon world-wide competition. Wood pulp is manufactured very largely from coniferous species. A recent study of the world's timber supply<sup>2</sup> shows that coniferous species supply nearly half of the timber cut in the entire world, but that they occupy only a little more than one-third of the world's area of forest land. Furthermore, the current growth of conifers is less than four-fifths of the cut. The critical world's timber-supply problem of the next half century at least will center in the coniferous forests.

While the general demand for coniferous timber has been expanding to a total which exceeds the replacement by growth, the world's paper consumption has also been increasing with unbelievable rapidity. The world paper consumption curve in Figure 22 gives the appearance of a distorted vertical scale, until one realizes that the phenomenal rate of increased consumption in the United States has been approximately doubled by that of all countries combined. Along with this rapidly expanding world demand must be taken into account the limited amounts which other countries can supply. Sweden is already removing the full annual growth from her forests and Norway is overcutting hers. The Finnish forests as a whole are being overcut. Many observers foresee the limit of the expansion of the eastern Canadian industry. Apparently the only country in the world outside of the United States which offers the opportunity for a long sustained increase in pulp-wood supplies commensurate with the increasing world demands is Russia, including Siberia, and a large part of the Russian forests are inaccessible.

A reconstructed Europe will need more paper than it can purchase now. New paper markets are being created. The reawakening of the Near East and the Orient, the development of Latin America, the settlement of the parts of the world heretofore unoccupied, are all accompanied by increased requirements for paper. If, therefore, the United States elects to depend upon foreign supplies, we must look forward to increasing world competition, higher prices, and restricted amounts in years to come, even though there is no conscious effort by foreign countries or industries to shut off our imports or control their prices.

The part of our own land area which is valuable only for timber production should be used in ways which will contribute most largely to our national prosperity. Regions with large areas of forest land can be made centers of the same permanent development as areas of rich agricultural lands. Both produce crops which differ only in kind. A thriving timber-growing industry is as basic in its character as agriculture. Upon timber crops can be founded permanent local wood-using industries, such as pulp and paper manufacture. Timber growing and its dependent wood-using industries can supply the livelihood for a large rural population of the character that adds so greatly to national strength.

<sup>2</sup> Forest Resources of the World, by Zon and Sparhawk.

Extensive areas of idle forest lands are a public burden. As long as they remain idle, transportation facilities can not be supported, the taxes on productive property are increased, settlement is hampered, and social progress is retarded.

The desirability of becoming independent of foreign countries for pulp wood, pulp, and paper rests fundamentally, however, upon the possibility of growing pulp wood and manufacturing pulp and paper more cheaply than foreign products can be imported. The feasibility of domestic production must in the last analysis rest upon cheaper products to the ultimate consumer.

European pulp-wood supplies now come from cultivated forests. Canadian supplies will soon also have to be grown by forestry if they are to remain a factor of importance. Upon large areas in the United States suitable only for timber growing occur many species eminently satisfactory for pulp. The United States has on the whole much more favorable growing conditions than either eastern Canada or northern Europe, the main sources of our imports. We should therefore be able to secure larger yields in shorter periods from our own land. Upon foreign-grown materials now and in the future, the American consumer must in general pay higher freights than from our own territory. We have forest land and pulp species in abundance, and in addition are more favorably situated than any other country in the world for the remaining essentials of paper making. Water power is available in large quantities. Coal deposits will furnish supplemental power wherever needed. Such other materials as sulphur, caustic soda, limestone, and the bleaching chemicals may be secured within our borders. The alum and rosin needed for "sizing" and the clays for "loading" paper are all domestic products. Since timber is the only material used in pulp and paper making which may be lacking, it should be to the advantage of the final consumer in cheaper products to grow the timber and manufacture pulp and paper at home. Finally, the more nearly independent we can become the less likely we are to be subject either to dictated prices from outside sources or excessive prices resulting from world competition.

For the period during which paper or its constituent materials can be obtained more cheaply by American consumers from foreign than domestic sources, their importation is a sound measure of forest conservation. They will eke out our diminishing supply of convertible pulp wood. But looking forward to the coming world-wide shortage of these materials, with its reactions upon cost and upon the policies of foreign nations, the only sure way to supply our future paper requirements abundantly and cheaply is to utilize our own natural advantages for producing them on American soil.

Since the significance of all these considerations is magnified by the economic importance of the services which paper renders, this question is next discussed.

## **CURRENT AMERICAN REQUIREMENTS: HOW THEY ARE SUPPLIED.**

### **CURRENT REQUIREMENTS AND THEIR IMPORTANCE.**

In 1922 the people of the United States consumed more than 8 million tons of paper, more than all other countries in the world combined. In the manufacture of this total the industries of the United States and of several other countries utilized about 5,847,000 tons of new wood pulp, which in turn was secured from about 9,148,000 cords of pulp wood. (Table 1.) In addition the United States reused in its own mills in 1919, the last year for which data are available, slightly in excess of 1,850,000 tons (Table 2) of waste paper, in which wood pulp constituted 85 per cent of the raw material.

Consumption of nonforest materials, though important for specialized products, is relatively small. We used in paper manufactured in the United States in 1919 slightly more than 275,000 tons of rags, 115,000 tons of manila stock, 350,000 tons of straw, and 105,000 tons of all other nonforest materials. How insignificant in volume all these materials are in comparison with wood in present-day paper manufacture is shown graphically in Figure 1.

The importance of continued supplies of raw material for paper must be measured not by the drain of the paper industry upon the forests as compared with that for lumber, fuel wood, and other timber products, but by the part that paper plays in our national life. Newsprint paper has for many years been made exclusively of wood pulp. Our 1922 consumption of more than 2,450,000 tons of newsprint (Table 3) constituted 31 per cent of our total paper requirements. Book paper derives more than 75 per cent of its raw material from the forest, and in 1922 comprised more than 12 per cent of our total paper consumption.

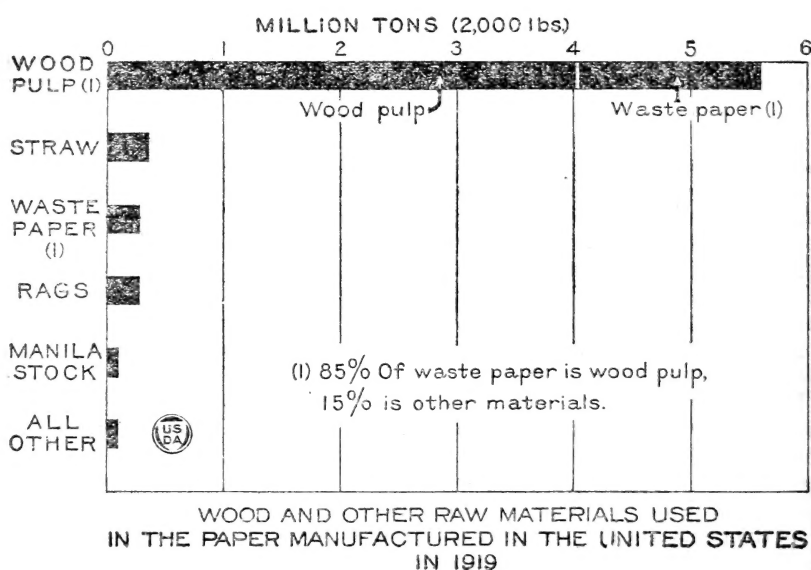

FIG. 1.—Wood supplied over 90 per cent of the raw material for the paper made in the United States in 1919. Wood pulp, which leads all other materials, is supplemented to an important extent by waste paper, 85 per cent of which is derived from wood.

While the bulk of paper consumption is for purposes distinct from its outstanding function as material for the printing press, it is on abundant and cheap supplies of print paper that the interest of the public is now overwhelmingly centered. Cheap newsprint has made it possible for the press to attain its present commanding place in our national life as an agency for the diffusion of information and the creation of an enlightened public opinion on important questions. Book paper, constituting as it does the medium for most magazines as well as books, plays a part in public education the importance of which is obvious and fundamental.

But newsprint and book papers make other contributions to current life. The structure and conduct of modern business in all of its infinite ramifications depends in no small degree upon the facilities afforded by paper and printed material. The fine papers, with a consumption in excess of 350,000 tons, very largely writing papers, may also be classed with newsprint and book in their economic and public benefits.

The widely varied group of papers classified under boards consumed in 1922 a volume almost equalling newsprint, 27 per cent of the total for the year. Its services have merely been more recent and possibly less spectacular than those of the printing and writing papers. Its uses range from the small, highly specialized packages used in the distribution of food and other products to the heavy, strong material which plays such an important part in making our homes more comfortable. Wrapping paper, which in 1922 passed the million-ton mark, finds also a wide range of usefulness for business purposes and is scarcely less essential to the public health for the more sanitary handling of food.

The wide range and varied uses of "all other" papers in everyday civilized life is barely suggested by naming a few of those which constitute the group: Blotting, hanging, fiber, carbon, copying, tissue, fruit wrapping, crêpe, wax, onion skin, oiled, cigarette, insulating, manila, imitation parchment, novelties, cartridge, cork, stencil, leatherette, carpet felting, grease-proof, tar, and building paper. The demand in 1922 for these and other papers of the "all other" group aggregated in excess of 1 million tons.

### THE DEVELOPMENT OF THE AMERICAN INDUSTRY.

Pulp and paper making in the United States, and in fact throughout the world, falls into two well-defined periods. During the first no wood at all was used, while during the second wood has supplied an increasingly large percentage of the raw material. The first period persisted until the late sixties of the past century.

#### PRIOR TO THE USE OF WOOD.

Paper making in the American Colonies is reported to have begun with a mill in Philadelphia, first operated in 1690. The shutting off of European paper during the Revolution greatly stimulated development and at its close the number of mills had increased to 80 or 90. By 1810 there were approximately 200 mills in the United States, and by 1850 there were 443. The early mills were small affairs employing but few hands and ordinarily supplying only local demands. One of the best in the Colonies in 1775, nearly 100 years after the first was built, reported a daily output of from 230 to 250 pounds of paper, contrast enough with the 1,600 times greater capacity of a modern newsprint plant which can produce 200 tons a day.

Colonial paper consumption was very small. Publication of the first newspaper began in 1704. The volume of correspondence hardly justified the existence of the small, unorganized colonial posts. Paper and books were luxuries even for the well-to-do. Approximately 3,000 books, pamphlets, etc., mostly small and with limited editions, are estimated to have been printed in all the Colonies up to about the time of the Revolutionary War, and the number of newspaper issues, none of which exceeded a few thousand copies, was approximately the same. The whole range of paper use was in fact exceedingly meager and restricted compared with that we now know.

As contrasted with paper production in American mills of more than 7 million tons in 1922, the output of 1810 is estimated at 3,000 (Table 4). By 1819 production had more than quadrupled, while during the last century it has increased approximately five hundred sixtyfold. The Civil War with its stimulus for news tripled the paper production of 1859 to the 386,000 tons of 1869. This marks the end of the period during which paper was made exclusively of other materials than wood. The final output was only 5 per cent of that of American mills in 1922 and a still smaller part of our consumption during the latter year.

Until 1859 linen and to a lesser extent cotton rags were the outstanding raw material for paper making in the United States as in Europe. All linen consumed

in the United States was imported, and there were periods of great scarcity during which the mills were unable, despite the most energetic measures, to obtain the rags needed to meet their requirements. This was reflected by serious paper shortages. During the Revolution American officers were often unable to obtain the insignificant amount of paper needed for orders. Newspapers were frequently published on paper of different colors and on sheets of different sizes, and editors were sometimes forced to print even the margins. Then and later colonial, State, and congressional legislative committees made special inquiries; there were a long series of appeals to the public to preserve rags for paper making, prizes were offered to stimulate research for other raw materials, and patents were issued for pulping cornstalks and many other materials. A process by which straw could be utilized for paper was perfected in 1825, but it was little used until Civil War requirements increased consumption by leaps and bounds.

As in practically all early industry, paper manufacture was largely by hand. Until approximately 1825 man power was used except in the beating engines which were gradually introduced, and for these water supplied the power. The various types of machinery which make possible production on its present scale were introduced in primitive form between 1825 and the middle of the century, so that by 1850 paper consumed in the United States was very largely machine made.

#### THE WOOD-PULP PERIOD.

Although the soda and mechanical processes of making pulp from wood were introduced into the United States during the late sixties and the sulphite process was discovered in 1867, none of these processes was extensively used until after the expiration of patent control 17 years later. The first sulphite mill began operations in 1882 and the first sulphate mill as recently as 1908. A brief statement of the nature of the pulp processes will be helpful to the reader not thoroughly familiar with pulp and paper manufacture.

In the soda, the first of the three chemical processes introduced, chipped wood is cooked in a solution of sodium hydroxide. Under this process the comparatively short-fibered hardwoods, such as aspen, yellow poplar, basswood, and the gums, are reduced. Soda pulp is used almost exclusively in book and the fine papers, to give body. The mechanical, sometimes called the groundwood, process introduced about the same time is based upon an entirely different principle. It reduces such coniferous woods as the spruces and true firs by abrasion against a rapidly revolving stone. Mechanical pulp is used mostly to give body to newsprint and similar papers, and because of its comparatively low cost and the large percentage used, helps to keep the prices of these papers at a low level.

The sulphite was the second chemical process to come into use. It depends upon a cooking solution of bisulphite of lime and produces long-fibered pulp from such woods as the spruces, the true firs, and the hemlocks. This pulp is used to give the requisite strength to newsprint, book, and the fine papers. Sulphite finds, therefore, the most general use of any of the wood pulps.

The third chemical process, the sulphate or kraft, is very recent in application. It uses sodium hydroxide and sulphide in cooking, and from the hard pines, larches, etc., produces a very strong pulp, the standard use of which is for wrapping paper, but which also is an important constituent of boards.

Because of the nature of the solution ordinarily used the soda and sulphate are sometimes called the alkaline processes and the sulphite the acid process. The so-called pulp grades take their names from the particular process—soda, sulphate, sulphite, or mechanical—employed in making them. It is upon these four pulping processes that the growth of paper production in the wood-pulp period is based.

Pulp wood made its first appearance in the census reports of 1869, but contributed only a little more than 2,000 cords to the raw materials used that year in manufacturing approximately 386,000 tons of paper. (Tables 4 and 5.) Before the end of the next 20 years the great growth of the American industry had begun and by 1889 paper output of the mills had passed 930,000 tons. It doubled again during the following decade, and more than tripled between 1899 and 1922.

In short, paper making in great volume became possible with the use of wood. Wood-pulp processes revolutionized both paper making and paper use in the United States and in the whole world. The rapid increase in world paper production since 1895, shown in Figure 2, is based on wood. But while the wood-pulp industry in the United States developed at a phenomenal rate and paper production increased in quantities previously undreamed of, consumption of paper increased still more rapidly. The slowly increasing consumption prior to 1880 and the transformation that followed, especially after 1890, are brought out by Figure 21.

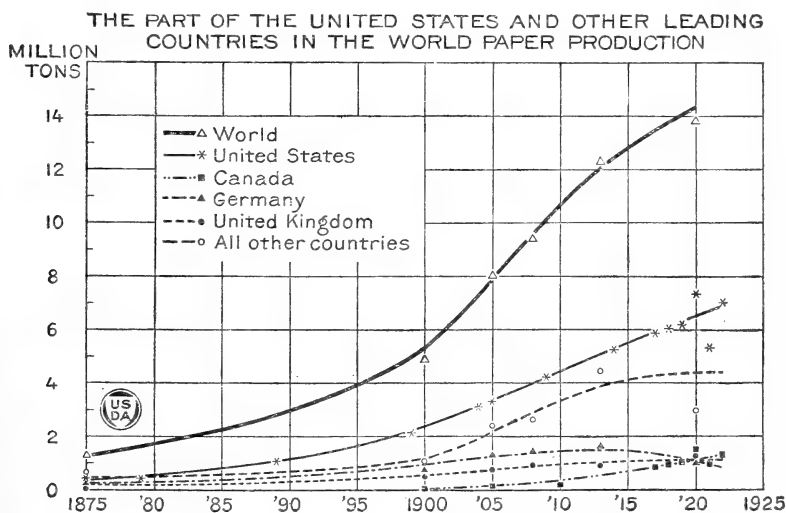

Fig. 2.—The United States in 1920 manufactured more than half of the world's paper, and has in fact led all other countries in production for virtually the entire period for which data are available.

Notwithstanding the great size attained by the American pulp and paper industry in comparison with those of other countries it has developed to a remarkable extent in very restricted regions. The processes now used for both mechanical and sulphite pulp require a soft, light, easily bleaching, long-fibered wood relatively free from pitch. The mechanical process demands in addition the cheap and abundant power which water alone can supply, while for the chemical processes fuel is essential. Nearness to paper markets has been necessary to keep down transportation costs. The spruce forests in New England and New York have met these combined requirements better than those of any other sections of the United States, so that it has been here, and later in smaller degree under similar conditions in the spruce and hemlock forests of the Lake States, that the American industry has largely centered. This development has also carried with it a considerable part of the sulphate-pulp industry, which could have located elsewhere and made use of other species. Even the soda-pulp industry, which began and is now well developed in Pennsylvania, manufactures a large part of

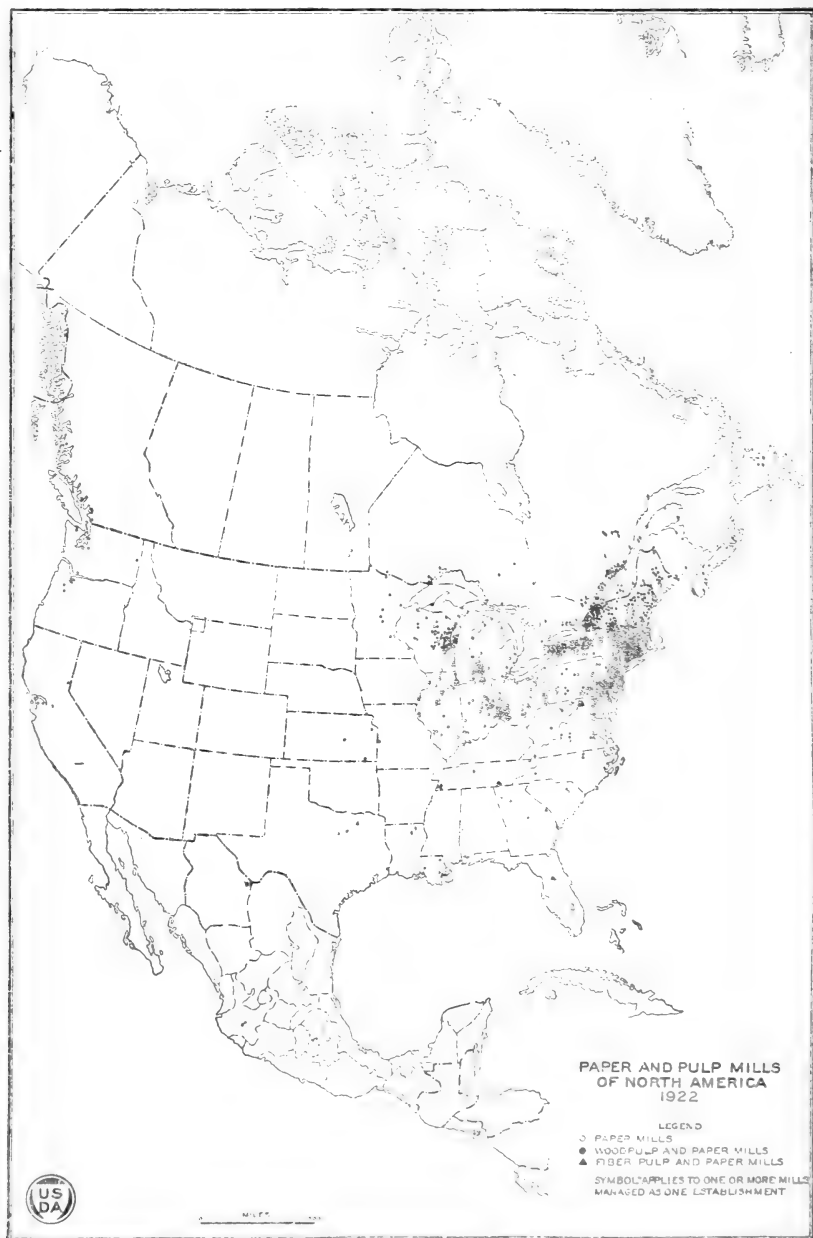

FIG. 3.—The pulp and paper mills of the United States are largely concentrated in the New England, Middle Atlantic, and Lake States, in and tributary to forests of spruce, fir, and hemlock. Few mills are located in Alaska, the Pacific coast, and Southern States, which have much larger pulp-timber resources.

its product from the aspen<sup>3</sup> in the spruce forests. The character and the extent of the centralization need not be discussed further here but are shown graphically in Figure 3 and numerically in Table 8.

This centralization, in fact overcentralization, intensifies the problem created by the imports from other countries of pulp wood, pulp, and paper, and it is the chief factor in the situation which necessitates pulp-wood imports. Analyses of imports from foreign countries both of raw pulp wood and of manufactured pulp and paper will be made in the following sections. A general explanation here, however, of the complex situation that exists in pulp wood, pulp, and paper imports and in the combinations in paper manufacture of pulps derived from wood and from other materials may clarify the facts.

We cut a large volume of domestic pulp wood, manufacture it into wood pulp, and then into paper. But we import a large amount of pulp wood each year from Canada, which is mixed with and follows the same course of manufacture as our own. We also import a large amount of wood pulp each year from Canada and several north-European countries. This imported pulp mingles with the product of home-grown timber and imported Canadian pulp wood in the manufacture of various so-called grades of paper in American mills. Still further, large aggregate paper imports from Canada and several European countries compete in the American markets with the product of American mills, which as previously indicated utilize both domestic and foreign raw materials.

The chief grades of paper only—book, wrapping, boards, and newspaper—are considered in detail in this report. The four grades of wood pulp, combined in different proportions, make up or help to make up these and other grades. A large and rapidly growing use of old paper of all kinds (85 per cent wood) mingles with new pulp in various papers. The manufacture of distinct pulps and papers from raw materials other than wood and the combination of wood and nonwood pulps complicate production still further. Linen rags from foreign and cotton rags from home sources are, for example, mixed with sulphite and soda pulp in various fine papers. Straw, on the other hand, entirely native, is used in the manufacture of a special class of boards. Imported manila stock goes into special kinds of manila paper. Finally, we export varying amounts of a number of pulps and papers. These involved relationships may be traced in Figure 4.

## HOW PRESENT AND PAST REQUIREMENTS HAVE BEEN MET.<sup>4</sup>

Between 1869, the first year that wood-pulp production was reported, and 1922 the manufacture of paper in the United States increased 18 times while its consumption increased more than 20 times. American paper mills, in other words, were unable during this period to keep pace with the acceleration in consumption; imports of paper increased nearly 80 times in value and the difference between production and consumption has now reached about 1 million tons. But at the same time that American paper production was falling behind consumption American pulp mills, supplied though they were with imported as well as domestic wood, fell rapidly behind the demand of the paper mills, so that pulp imports, only a little more than 25,000 tons in 1889, had increased to more than 1½ million tons in 1922. And finally, the pulp mills in turn have had to meet their growing

<sup>3</sup> Aspen is used throughout this report for the species commonly known in the pulp and paper industry as poplar.

<sup>4</sup> The data used in the analysis of our imports, outside of those available from census reports and Bureau of Foreign and Domestic Commerce reports of imports and exports, have been derived by use of such known relationships as that of cords in pulp wood to tons of pulp of the different grades and that of the average proportions of the different grades of pulp in various grades of paper. While the resulting figures are not absolutely accurate, both current relationships and trends up to the present time are shown concretely and it is believed closely enough for all practical purposes.

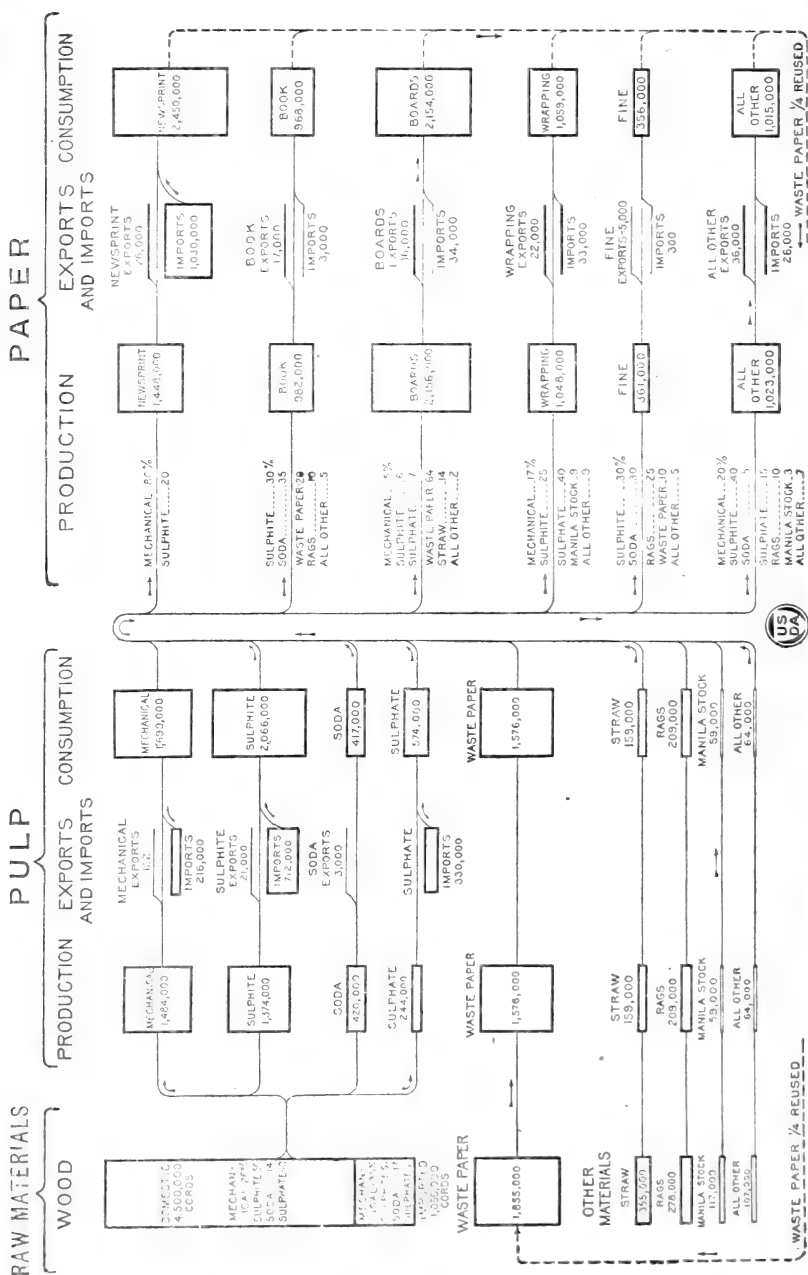

FIG. 4. Amounts in tons, except for pulp wood.—To permit comparison, pulp wood although stated in cords is plotted in tons. The involved relationships between raw materials, pulp, and paper are further complicated by imports and exports. The rectangles followed horizontally show, with the connecting lines, the course from raw material to final product, while followed vertically the rectangles show the comparative volume of various raw, intermediate, and final products. The data on pulp wood and its products are for 1922, and that for other materials and their products are for the closely similar year of 1919.

volume of pulp-wood requirements partly through pulp-wood imports, which probably began as early as 1895, and since 1912 have ordinarily exceeded 1 million cords a year

Stated in another way, our paper industry in 1922, manufactured more than 7 million tons of paper from domestic and foreign supplies, but we consumed 8 million tons. Our pulp industry manufactured  $3\frac{1}{2}$  million tons of pulp, in part from imported wood, but 5,847,000 tons were required for our total paper consumption. Finally, we cut from American forests  $4\frac{1}{2}$  million cords of wood, but the total consumed in the United States and elsewhere to meet our paper requirements was 9,148,000 cords of domestic and foreign wood. Only 88 per cent of the paper consumed in 1922, was manufactured in the United States; only 60 per cent of the pulp used in making the paper consumed was a home product; and only 49 per cent of the wood used in meeting paper requirements

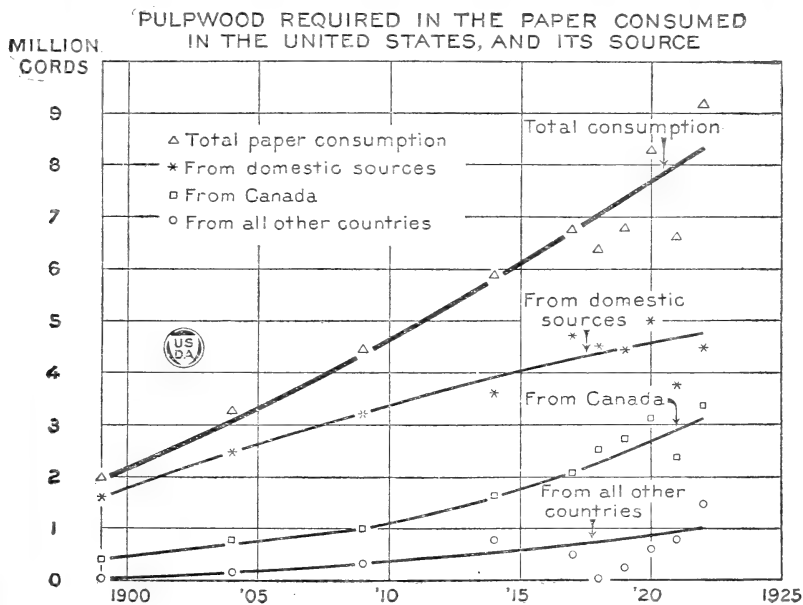

FIG. 5.—The gradual parting of the curves representing total pulp-wood requirements and the pulp wood secured from domestic sources shows strikingly the growing volume of imports. The contribution of the Canadian forests supplied in the form of paper, pulp, and pulp wood is increasing more rapidly than that of our own.

came from our own forests. These figures indicate specifically the extent to which American paper mills, pulp mills, and forests, respectively, now fall short of meeting national needs for paper.

Hardly less important than the extent of our present imports from foreign sources is the rate at which they are increasing. As recently as 1899, little more than two decades ago, American forests furnished 83 per cent of the wood for our paper. (Table 10.) Imports have since been increasing at the rate of about 192,000 cords a year. The outstanding fact to-day is that more than half of the forest materials for all the paper used in the United States comes from outside our boundaries. The curve in Figure 5 which indicates domestic pulp wood has been gradually flattening since 1905, while those indicating all pulp wood, pulp, and paper imports from Canada and from other countries converted to pulp wood, for comparison are still rising rapidly. The growth, present extent,

and character of the dependence of the United States for the wood required in our paper is further shown in Figure 6, while the part of total requirements secured from domestic and foreign sources is shown in Tables 10, 11, and 12.

This general background affords a better basis for the consideration of pulp-wood imports.

#### PULP WOOD.

It took 9,148,000 cords of wood to supply our 1922 paper requirements, of which about 4,498,000 cords were cut from our own forests. We exported an equivalent of 235,000 cords. Pulp-wood imports amounted to nearly 1,045,000 cords (Table 34) and hence furnished 11 per cent of all the wood required and 19 per cent of all the pulp wood consumed in American mills. The remainder of our requirements, equivalent to 3,840,000 cords, was imported as pulp and paper.

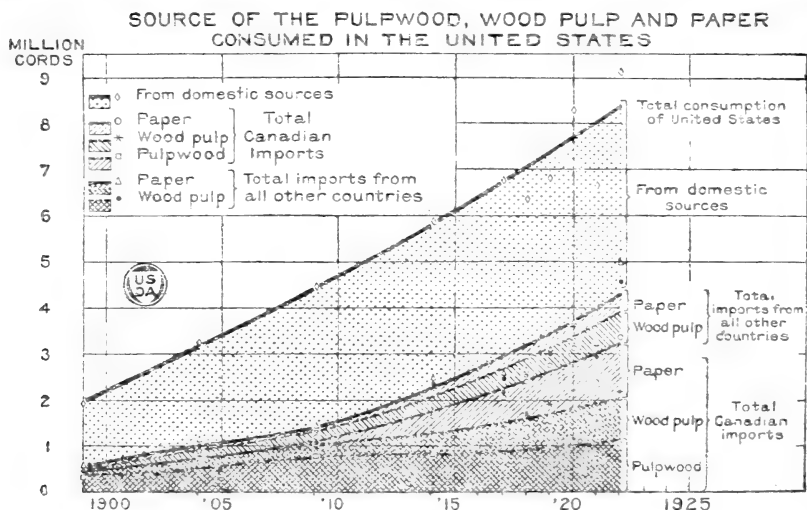

FIG. 6.—Increasing imports, particularly since 1900, have consisted almost entirely of pulp and paper. These products are being manufactured in other countries near the forests on which they depend. Total Canadian imports are nearly as large as the contribution from American forests. The data are shown in cumulative curves.

We import pulp wood from Canada alone, since it is the only country with suitable timber supplies near enough to make the payment of the freight costs economical. Pulp-wood importations began about 1895 in significant quantities and increased until about 1910, when they slightly exceeded 930,000 cords. Since that date there has been relatively little change. It was on May 1, 1910, that the pulp-wood embargo upon the Crown lands of Quebec, the Canadian Province best situated for importations to the United States, became effective.

The growth of pulp-wood imports corresponds roughly with the first part of the period during which the American industry was expanding with greatest rapidity. Imports began when American manufacturers were able to secure Canadian timber more easily than American, and when they began to realize the limitations in their own holdings and in American resources of their own regions.

Canadian imports consist chiefly of spruce with a certain amount of fir, which together make 83 per cent of the total pulp-wood imports and which go largely into sulphite and mechanical pulp. The remainder, 17 per cent, is aspen (Table 5) and constitutes practically the entire Canadian cut. It goes largely into soda pulp.

## WOOD-PULP GRADES.

The slowing down in pulp-wood imports naturally affects wood-pulp imports. The latter began in volume about 1900. While they increased gradually prior to 1910, their subsequent growth has been more rapid. Present and past requirements of the various grades of wood pulp and of the amounts of pulp wood necessary for each, on which the following detailed analysis is based in part, are shown in Tables 13 and 14 and Figure 7. Consideration is not confined to the imports of pulp as such, for it is equally important to learn what our dependence is for each class of pulp, whether importations take the form of pulp wood, pulp, or paper.

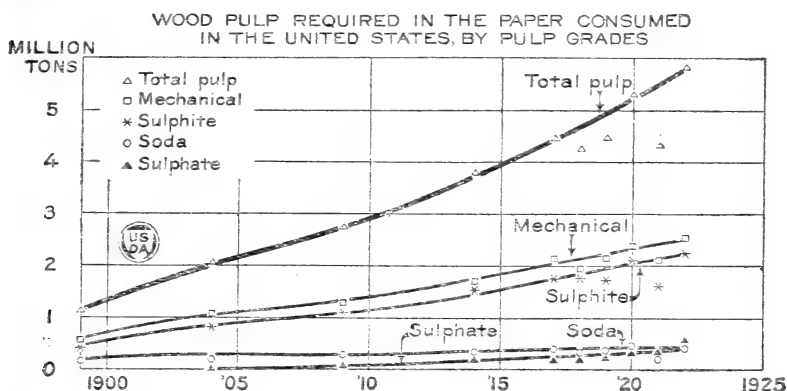

FIG. 7.—Requirements for mechanical and sulphite pulp are much larger and are increasing much more rapidly than for soda and sulphate pulp.

## SODA PULP.

Although pulp-wood requirements for soda pulp have more than tripled since 1899, they now constitute only about 759,000 cords (Table 15), or 8 per cent of the total needed each year for our entire paper requirements. Despite the fact that soda was the first wood-pulp process introduced into the United States, it has grown so slowly in comparison with other grades and absorbed so little wood that more than 600,000 cords, or 80 per cent of our total requirements, are secured from domestic pulp wood. A large number of hardwood species are suitable and they occur over an extended territory, in part remote from the Canadian border, so that relatively ample timber supplies are still available. Furthermore, many soda mills were located in rag-pulp centers before wood pulp reached its present importance, near most of which relatively large amounts of suitable hardwoods of a quality too low for use in most other industries are still available. It is not surprising, therefore, that the United States is more nearly self-supporting in the wood utilized in the manufacture of its soda than any other wood-pulp grade.

Aspen pulp wood from Canada is the chief item in imports of soda-pulp material. Nearly 180,000 cords were imported in 1922. (Table 5.) This was 99 per cent of the soda-pulp material which Canada furnished for that year, and Canada supplied approximately 92 per cent of our total importations. Since 1899 Canada's contribution, chiefly pulp wood for the entire period, has increased nine times. Pulp-wood imports amount, therefore, to about 92 per cent of 1922 imports of soda-pulp material in all forms, but, as will be shown later, it should be comparatively easy to secure an equal and even a much larger volume of soda-pulp woods from our own forests.

Imports of soda pulp, and of book paper, of which it is an important constituent, from both Canada and Europe are negligible. The United States exports offset imports in all forms by about one-fifth. The general trend of requirements and of the relative amounts of the raw materials secured from domestic and foreign sources is shown in Figure 8 and Table 16.

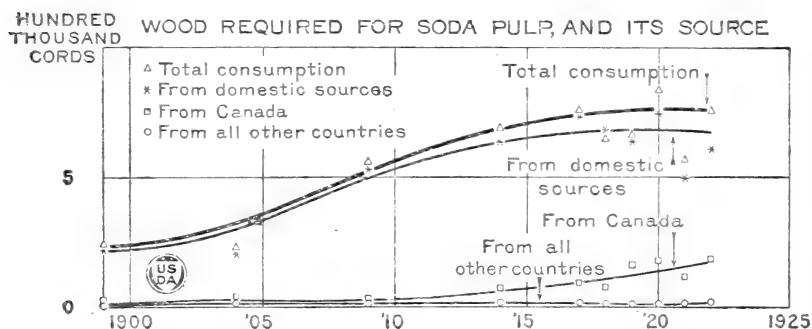

FIG. 8.—The United States is more independent of foreign sources for soda pulp than for any other kind. Eighty per cent of the pulp wood required is secured from American forests.

#### SULPHATE PULP.

About 1,220,000 cords of wood, or 14 per cent of the requirements of 1922 for all paper, went into sulphate pulp. The use of sulphate pulp in the United States began as recently as 1904, and the first domestic production was four years later.

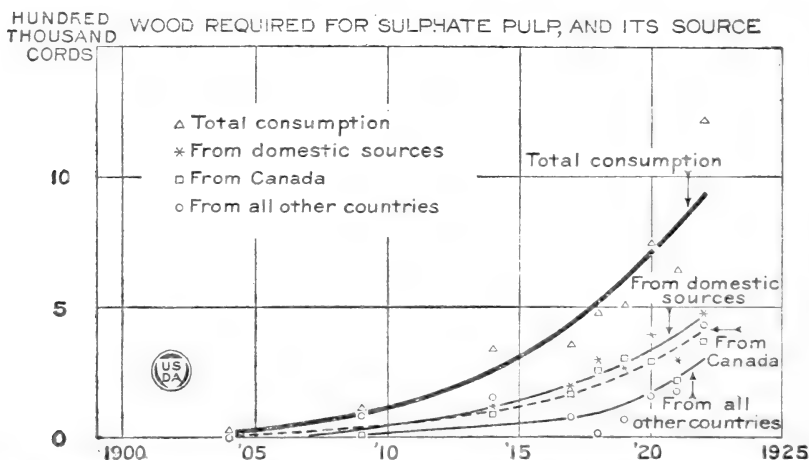

FIG. 9. Sulphate pulp was first used in the United States about 1904, and production in this country began four years later. Total pulp-wood requirements are now more than a million cords, 63 per cent of which comes from other countries.

The imports of pulp wood for sulphate pulp are very small, amounting to less than 2,000 cords in 1922. Imports of wrapping paper are also small, aggregating in 1922 a little less than 33,000 tons, half from Sweden and the remainder from a number of countries. With small amounts of both pulp wood and paper, it follows that imports must consist largely of wood pulp. Pulp, in fact, aggregated in 1922 more than 330,000 tons (Table 31) out of a

total dependence of 376,000 tons (Table 18). This is the only grade of wood pulp in which we are more dependent on Europe than on Canada. European countries, chiefly Sweden, Finland, Norway, and Germany, furnished in 1922 an equivalent of 35 per cent of our requirements in pulp wood. American forests furnished 41 per cent, and Canada 28 per cent.<sup>5</sup> (Table 17.) Exports were small.

Our relative dependence upon foreign countries in 1922 for sulphate imports in pulp form was as follows: Canada, 46 per cent; Sweden, 42 per cent; Finland, 8 per cent. Only these countries made shipments of importance.

A complete shutting off of pulp-wood imports would therefore affect only about 2,000 cords of wood used for sulphate pulp, on the basis of 1922 data. The general trend of requirements and the relative amounts of raw material from domestic and foreign sources are further shown in Figure 9 and Table 18.

#### SULPHITE PULP.

While half of the wood needed for paper in 1922 went into sulphite, the pulp tonnage of 2,278,000 falls below mechanical because of lower yields secured by

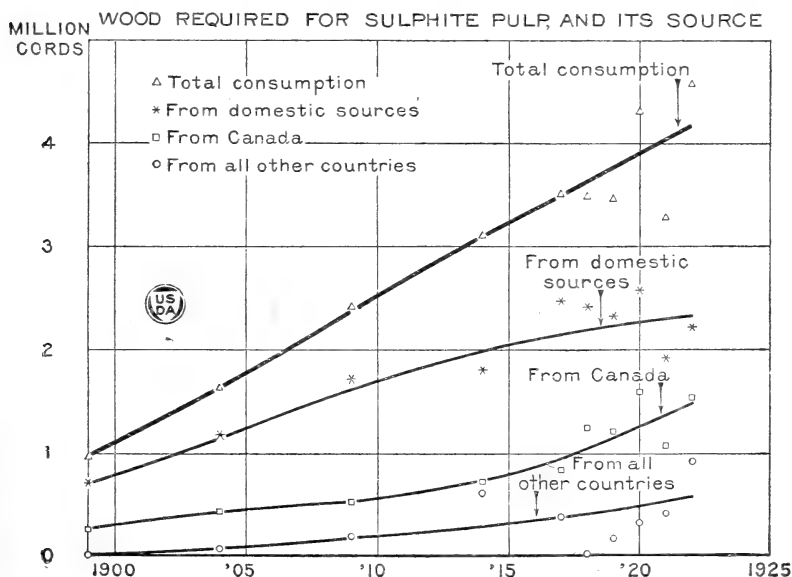

FIG. 10.—More than half of the pulp wood necessary for the sulphite pulp utilized in meeting American paper consumption is of foreign origin. Imports are greater than of any other kind of pulp and are increasing by an equivalent of nearly 100,000 cords a year.

the chemical process. Wood requirements for sulphite have increased nearly five times since 1899, and by more than  $3\frac{1}{2}$  million cords. (Table 19.)

Native forests supplied only 48 per cent of the pulp wood needed for sulphite in 1922. This is in striking contrast with 1899, when these forests furnished 75 per cent. Our largest imports are from Canada, which in 1922 shipped as pulp wood, pulp, and paper the equivalent of more than  $1\frac{1}{2}$  million cords of pulp wood, approximately one-third of total requirements and 63 per cent of imports. Exports were small.

Unlike either soda or sulphate, a large volume of the sulphite pulp consumed is imported in paper. Approximately 1,030,000 tons of newsprint paper, con-

<sup>5</sup> The percentages in this and similar cases are percentages of consumption and total more than 100 because some paper is exported.

taining about 20 per cent of sulphite pulp, were imported in 1922. Of this paper Canada supplied 87 per cent. The total volume of sulphite imported in paper of other kinds is too small for comment.

Sulphite imports as pulp were considerably larger than in paper, aggregating slightly over 710,000 tons in 1922. (Table 32.) Of this, Canada supplied 42 per cent, Sweden 37, Norway 11, and other countries small amounts. Reduced to pulp wood, the pulp imports would therefore represent about 1,560,000 cords.

Five hundred and fifty thousand cords of the pulp-wood imports from Canada were used for sulphite pulp. This figure, which is larger than for any other pulp grade, measures the volume which we must secure from our own forests in order to be self-supporting in sulphite pulp wood. The sulphite-pulp relationships described are further shown graphically in Figure 10 and Table 20.

#### MECHANICAL PULP.

Mechanical pulp made up slightly over 2,580,000 tons of American pulp requirements in 1922, or 44 per cent, and constituted the largest pulp grade.

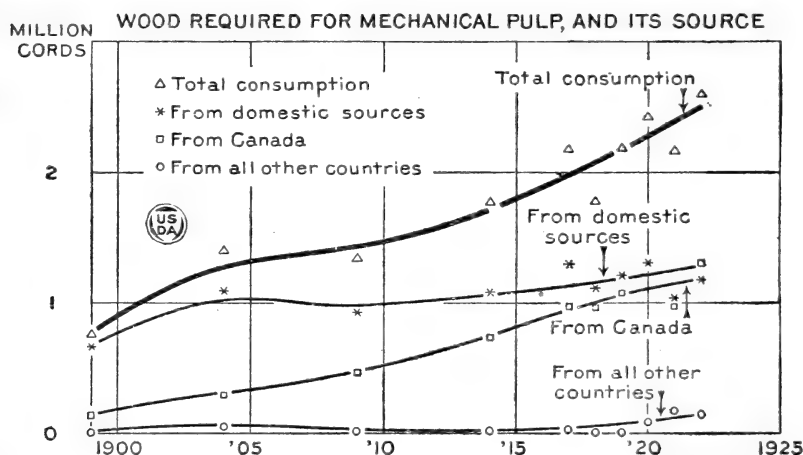

FIG. 11.—The amount of domestic pulp wood reduced by mechanical process has remained at practically the same level since 1901. The increased quantities necessary to meet American requirements have been imported chiefly from Canada in newsprint paper.

Since, however the yield per cord by the mechanical process is relatively high in terms of pulp wood, the 1922 requirements for mechanical pulp were slightly less than 2,600,000 cords, or only 28 per cent of the total.

Pulp-wood requirements for mechanical-pulp needs have become more than three times those of 1899, and the pulp-wood equivalent of imports in all forms has been multiplied by ten. Domestic pulp wood now supplies only 45 per cent of our mechanical pulp-wood requirements, and its contribution has increased but little in the last 20 years. Canada now furnishes 89 per cent of the imports, with the equivalent of nearly 1,300,000 cords of pulp wood. (Table 21.)

Transportation difficulties confine the small importations in pulp form almost entirely to near-by Canada (Table 33), and from there an equivalent of about 190,000 tons in 1922, or an equal number of cords, maintains a level which has held substantially since 1909 and 1910.

Newsprint paper imports of nearly 1,030,000 tons in 1922, 80 per cent of which is mechanical pulp, represent a pulp-wood equivalent of more than 900,000

cords. Eighty-seven per cent of this was supplied from Canada. Pulp-board imports in 1922 were less than 31,000 tons, and only about one-fifth of its material was new pulp, of which mechanical pulp formed only one-fourth.

Approximately 318,000 cords of the total pulp-wood imports from Canada in 1922 were utilized for the manufacture of mechanical pulp. The volume is second only to pulp-wood imports for sulphite pulp. The mechanical-pulp situation of the past 20 years is further shown in Figure 11 and Table 22.

Some of the preceding relationships between domestic pulp-wood supplies and imports in pulp wood, pulp, and paper form are summarized graphically in Figure 12 for all four pulp grades.

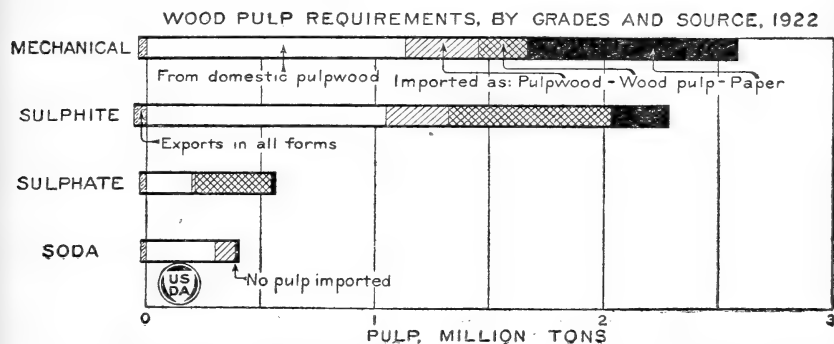

FIG. 12.—Domestic pulp wood supplies less than half the requirements for all of the mechanical, sulphite, and sulphate pulp consumed. It furnishes 80 per cent of the requirements for soda pulp. The greater part of the mechanical pulp secured from foreign sources is imported as paper. The greater part of sulphite and sulphate imports are in pulp form, while those of soda are in pulp-wood form.

#### PAPER GRADES.

The different grades of paper contain chiefly varying proportions of two or more grades of wood pulp. Accordingly the discussion of the source of pulp requirements forms a logical preparation for considering the source of the grades of paper, the final product to which they contribute.

#### BOOK PAPER.

Book paper is made on the average of about 40 per cent soda<sup>6</sup> and 35 per cent sulphite pulp.<sup>6</sup> Old book paper, rag stock, and limited quantities of other materials supply the remaining 35 per cent. Thus only about 725,000 tons of the total book-paper consumption in 1922 represented new wood-pulp requirements (Table 23).

The United States supplies from home-grown wood about 58 per cent of this new pulp. We depend upon Canada for 31 per cent and upon various European countries for 13 per cent. Exports of book paper are small.

The largest factor in our imports, totaling 27 per cent, and that which is growing most rapidly, is pulp, almost entirely sulphite, and a little more than half Canadian in its origin. It is equivalent to about 380,000 cords of the spruce-fir-hemlock group of pulp woods. Canadian pulp wood makes up about 17 per cent of our consumption, with approximately 130,000 cords of aspen for soda pulp and 140,000 cords of spruce and fir for sulphite. Book-paper imports are negligible.

The forests of the United States furnished 30 per cent less of the new wood materials for book paper in 1922 than in 1914. What is still more serious, the

<sup>6</sup> These average percentages differ slightly from those for a single year in Figure 4.

amount of American wood supplied fell off actually by about 185,000 cords as well as relatively, a disquieting situation which is brought out sharply in Figure 13.

The most urgent phase of the book paper problem on the basis of 1922 requirements is, therefore, to secure from our own forests each year additional amounts of about 130,000 cords of aspen for soda pulp and 140,000 cords of spruce for sulphite pulp and thus become independent of pulp-wood imports.

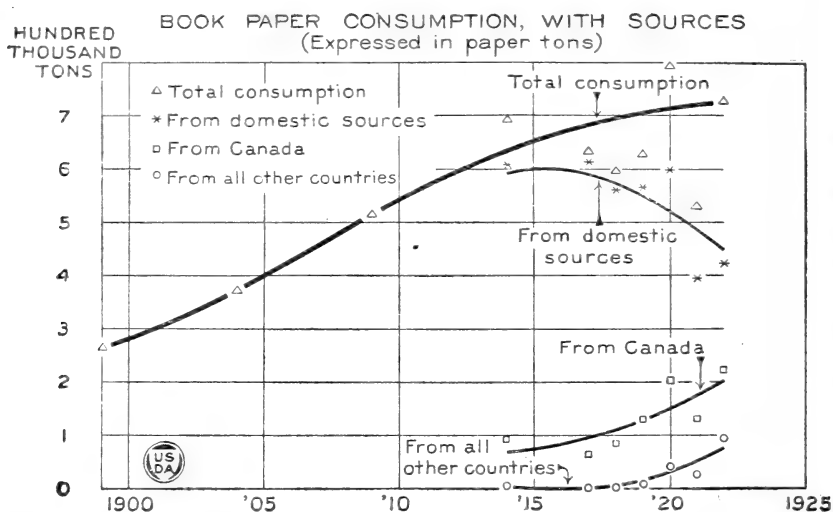

FIG. 13.—The amount of domestic wood used in the manufacture of book paper has fallen off rapidly since 1914, but this decrease has been made up and more by imports of pulp wood, pulp, and paper from other countries.

#### WRAPPING PAPER.

Wrapping paper averages in its composition about 40 per cent of sulphate pulp, 25 per cent of sulphite, 17 per cent of mechanical, 9 per cent of manila stock, and the remainder of other materials.

The United States is more nearly self-supporting in materials for wrapping than for any other class of paper, with 66 per cent of requirements coming from American forests in 1922. (Table 25.) Dependence for the remainder is divided about equally between Canada and Europe. Exports are small.

As in book paper, material for wrapping is imported mostly as pulp, a total of about 27 per cent, in approximately equal amounts from Canada and Europe. Paper imports are small and from Europe, while Canada supplies all the pulp wood, amounting only to 6 per cent, or about 130,000 cords of spruce and fir.

As in book paper, the United States has been increasing the volume of its imports. In the eight years following 1914 the use of American material declined 21 per cent, and, moreover, the actual amount declined about 140,000 cords. The trend is illustrated graphically in Figure 14.

#### BOARDS.

Although the total American "boards" consumption for 1922 falls short of newsprint consumption by only a relatively small amount, some 80 per cent of boards consists of all sorts of waste paper and straw. The 20 per cent of new pulp which normally goes into board manufacture meant, therefore, in 1922 about 430,000 tons in manufactured paper. (Table 24.) Sulphite, sulphate, and mechanical pulp each contributes about one-third to this new material.

Sixty-one per cent of the new pulp material was secured from American forests. We imported 26 per cent from Canada and about 15 per cent from Europe. Exports offset imports by only 2 per cent. As in both book and wrapping paper, pulp is the outstanding factor of the imports, totaling 27 per cent. Pulp

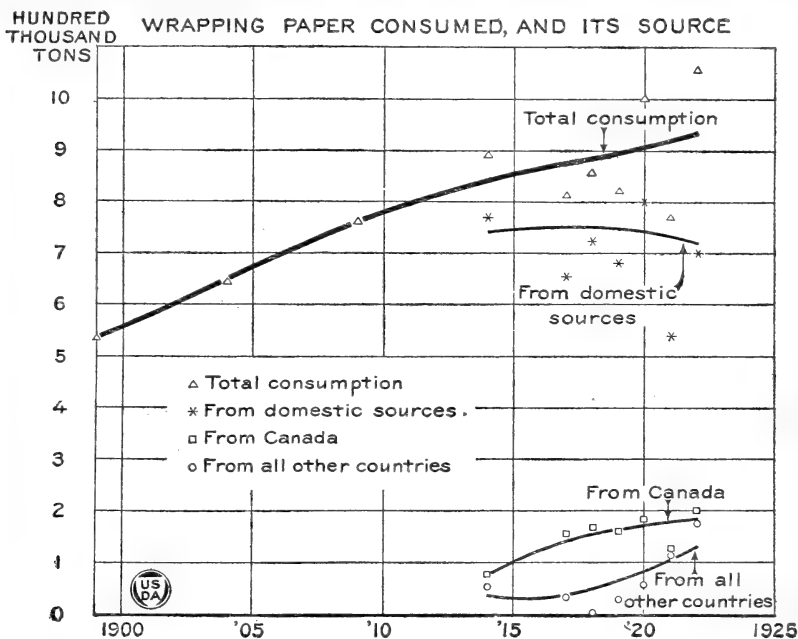

FIG. 14.—American materials used in producing wrapping-paper requirements show a slight downward tendency. Increased consumption, however, is being met by foreign supplies. Imports of wrapping paper or its materials are less than of any other paper grade

imports alone are expanding appreciably. There is a relatively small import of manufactured boards and a still smaller volume of pulp wood, only 6 per cent, and all from Canada. The 27,000-cord spruce and fir pulp-wood import is manufactured into mechanical sulphite and sulphate pulp.

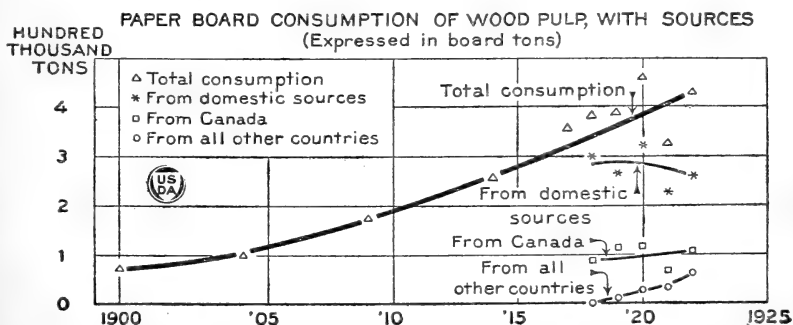

FIG. 15.—The amount of domestic pulp wood used in boards seems to be falling off slightly, but board consumption is still increasing very rapidly.

Our total dependence, as in the case of both book and wrapping paper, has increased both relatively and actually. In four years the contribution of American forests to board manufacture fell off approximately 80,000 cords. Figure 15 shows the decline.

Wood supplies 85 per cent of the raw materials which make up the waste paper contribution to board manufacture. For these wood materials we import from foreign countries the amounts indicated in the preceding and following discussion for the various pulps and papers. Our total dependence on foreign countries for raw board material is, therefore, in a sense considerably greater than the volume indicated for new pulp. Reuse, however, reduces the annual requirements for new material.

#### NEWSPRINT PAPER.

Eighty and twenty per cent represent the average contribution of mechanical and sulphite pulps to newsprint paper. Since we import as paper, pulp, or pulp wood 56 per cent of the mechanical pulp consumed and 54 per cent of the sulphite pulp, it is not surprising to find that a larger percentage of newsprint is imported than of any other paper grade. Consumption of newsprint in excess of any other paper grade emphasizes the significance of larger imports.

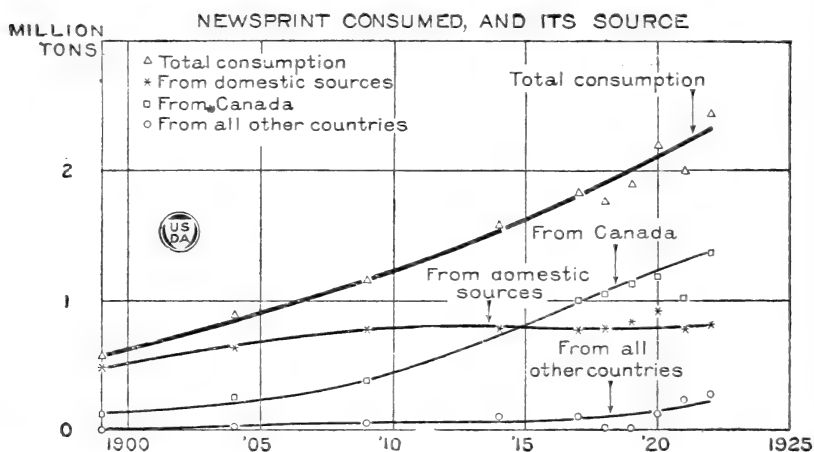

FIG. 16.—The United States is more dependent upon outside sources for its newsprint than for any other grade of paper. Since 1904 Canadian imports in pulp wood, pulp, and paper have met nearly all increased American demands, until now we draw more heavily upon Canadian forests than our own.

In 1899, little more than two decades ago, 83 per cent of the wood from which newsprint was manufactured came from home forests, but this percentage had in 1922 dropped to 34. (Table 26.) The only relieving feature is that the falling off of materials from American sources is relative only, not actual; the amount of domestic wood utilized for newsprint has increased about 450,000 cords.

Canada makes the outstanding contribution to our newsprint supplies, a total of 56 per cent of the amount consumed, or considerably more than the contribution of American forests, while all European countries together supply only 11 per cent. We export barely 1 per cent.

By far the largest imports are newsprint paper, a total of 42 per cent of the amount consumed, all but 5 per cent of which is from Canada. Canada, in fact, exported to the United States in 1922 nearly 83 per cent of its entire newsprint production. Imports of Canadian newsprint alone in 1922 exceeded the production from American wood, and this in spite of the fact that as recently as 1909 they totaled only 20,000 tons.

Pulp makes an additional contribution of 14 per cent, slightly more than half of which comes from Canada. Increase in pulp imports has been much

less than in newsprint paper, totaling for both Canada and Europe less than an equivalent of 325,000 tons of paper since 1899.

While total requirements have been growing at the rate of 82,000 cords a year since 1899, imports have been growing at the rate of 66,000 cords. Total imports in all forms, paper, pulp, and pulp wood, from all countries are equivalent to about 2,050,000 cords. Of this, 350,000 cords comes from Canada in pulp-wood form—more than for any other paper grade. An additional 1,375,000 cords comes from Canada in the form of wood pulp or newsprint. Figure 16 shows more strikingly than discussion the trend of the imports in comparison with the use of domestic pulp wood.

#### OTHER KINDS OF PAPER.

It is unnecessary for the purposes of this report to make similar analyses of our dependence for other kinds of paper. The amounts involved for any one class are relatively small, even though the totals for all kinds may be important. Furthermore, the complications encountered in such analyses are such as to make them extremely difficult and unsatisfactory.

Some of the preceding relationships between domestic pulp-wood supplies and imports in pulp wood, pulp, and paper form are summarized graphically in Figure 17 for newsprint, wrapping paper, book paper, and boards.

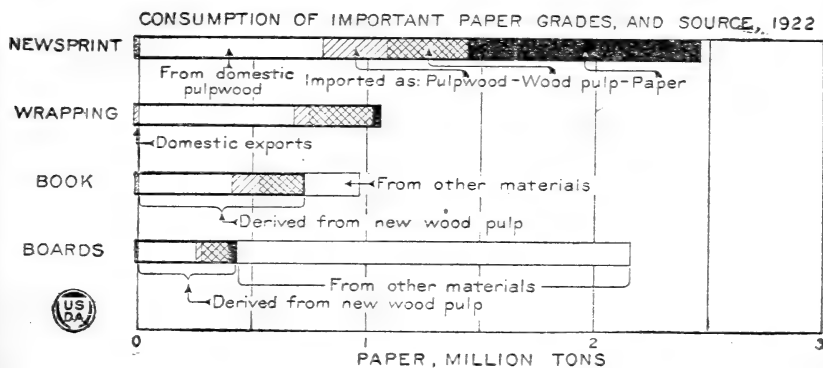

FIG. 17.—Only about one-third of the pulp wood required for newsprint paper is obtained from domestic sources. While imports of pulp and pulp wood are large, paper is by far the largest factor in newsprint imports. Two-thirds of the wrapping paper consumed is derived from domestic pulp wood, and pulp is the largest factor in the imports. Pulp is the largest factor in imports for both boards and book paper.

#### COUNTRIES.

Any analysis of our imports would be incomplete without a recapitulation by countries. Those of Europe form a logical group and are treated together. The discussion of Canada includes Newfoundland and Labrador.

#### EUROPEAN COUNTRIES.

Pulp and paper are imported from a number of European countries, but only Sweden, Norway, Finland, and Germany, in about the order named, are of particular importance. Imports from non-European countries other than Canada are so small that they are incorporated without materially influencing the totals. Altogether Europe in 1922 supplied an equivalent of approximately  $1\frac{1}{2}$  million cords of pulp wood (Table 27) or 17 per cent of the total of 9,148,000 cords needed for the entire paper requirements of the United States. Fully 96 per cent of these imports came from the countries named.

Because of distance and high freights, no pulp wood is imported from Europe, and only about 19 per cent of total imports in all forms comes as paper. It follows that the great bulk of imports from Europe, 81 per cent, are pulp.

Book paper is secured only in relatively small amounts. The tonnage of wrapping imports is considerably larger, a total of about 33,000 tons, and one-half is from Sweden. Among the papers newsprint moves to the United States in largest volume, totaling for 1922 about 135,000 tons and ranging downward from a little over 50,000 tons from Sweden to lesser amounts from Germany, Finland, and Norway, and to very small shipments from other countries. (Table 38.)

The pulp-wood equivalent of pulp shipments reaches nearly 1,225,000 cords, 67 per cent of which is sulphite, 29 per cent sulphate, and only 4 per cent mechanical. Sweden is as far in the lead in pulp shipments as in paper, with approximately 68 per cent of the total, and Norway is second with 15 per cent. Additional data showing the sources of European pulp and paper shipments to the United States in 1922 are not of sufficient importance to warrant discussion but are shown in Table 40.

Imports have made up quickly the serious interruption occasioned by the World War. The pulp-wood equivalent of approximately 38,000 cords in 1899 from all European countries had increased fortyfold by 1922. The sulphite and mechanical pulp and the newsprint imports are derived from the spruce group of pulp-wood species, and in 1922 were equivalent to about 1 million cords of wood, or two-thirds of the total imports. Shipments of wrapping and sulphate, which can be secured from pine, were, on the other hand, equivalent to only approximately 500,000 cords. Figures 5 and 6 illustrate the growth of imports from European countries.

#### CANADA.

Annual imports of pulp wood from Canada now total a little more than 1 million cords. But our total imports derived from the forests of Canada in 1922 were in the neighborhood of 3,374,000 cords, as shown by Table 28. This is 37 per cent of our total requirements, and is only 12 per cent below the volume of material supplied to American users by American forests. It is more than twice the volume furnished by all other countries. It is a growth of about 128,000 cords per year, or nearly 3 million cords since 1899, when the 420,000 cord import equivalent was only 22 per cent of total American requirements.

Although when reduced to pulp wood, paper imports from Canada in 1922 exceeded pulp, and pulp in turn exceeded pulp wood, the spread between the high and low barely exceeded 150,000 cords. There has been relatively little increase in pulp-wood imports since 1909. But wood-pulp imports during the same period have increased approximately 4 times, while the tonnage of paper is larger by nearly 55 times. The relative rates of increase of pulp wood, pulp, and paper imports for Canada are further shown in Figure 18.

More in detail, pulp-wood shipments now range somewhat above 1 million cords, of which 83 per cent is of spruce and fir and the remainder of aspen. The pulp imports include a little over 300,000 tons of sulphite, a little over 190,000 tons of mechanical, and 154,000 tons of sulphate pulp. These quantities represent, respectively, about 13 per cent, 7 per cent, and 26 per cent of our total consumption of each grade. Book-paper imports are negligible. Boards total less than 30,000 tons, while newsprint aggregates more than 895,000 tons, 37 per cent of our requirements for this paper, and about 70,000 tons more than we produce in the United States from American wood.

Altogether imports in 1922 of pulp wood, pulp, and paper derived from spruce and fir represented 2,850,000 cords, of which, as already indicated, 870,000 cords were in pulp-wood form. Total imports derived from aspen, the raw material for soda pulp, amounted to 196,000 cords, and 92 per cent of this entered the country in pulp-wood form. Imports from Canada are further shown in Figures 5 and 6.

**GROWTH OF CANADIAN IMPORTS OF PULPWOOD.  
WOOD PULP AND PAPER BETWEEN  
1899 AND 1922.**

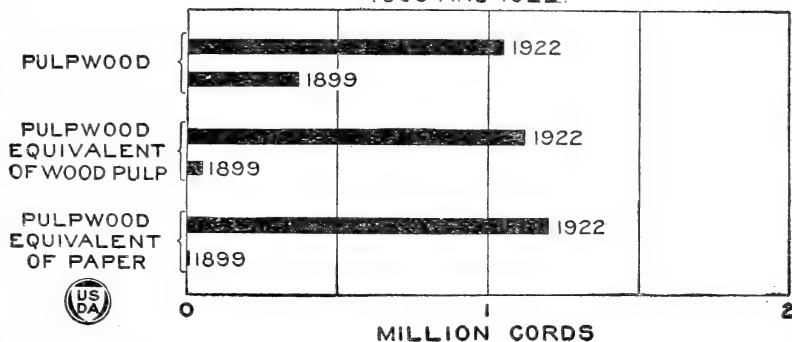

FIG. 18.—The United States depended on Canada about equally for pulp wood, wood pulp, and paper in 1922. As late as 1909 pulp wood constituted our only import of note. Pulp and paper imports are now growing by leaps and bounds, while pulp-wood imports are practically at a standstill.

**SPECIES AND GROUPS OF SPECIES.**

The foregoing analysis of the contribution of domestic supplies and imports to our requirements has proceeded from pulp wood through the various grades of pulp and paper to the countries from which the imports have been secured. There remains the need for a summation of our total pulp and paper requirements and imports in terms of cords of the species or groups of species of the woods utilized for each pulp grade. Such a summation will make it possible to relate the entire question of requirements and imports back to the forests, its fundamental source. It is indispensable in pointing out the forest regions of the United States which afford the most favorable conditions for the increased cut needed to offset both pulp-wood and total imports.

For our entire sulphate consumption we needed about 1,220,000 cords of wood in 1922. Spruce, fir, and hemlock have been used to a greater or less extent for sulphate pulp, but the hard pines and larches make a pulp which is entirely satisfactory for most purposes. It would require only about 2,000 cords of jack, southern, and western pine to meet current pulp-wood imports for sulphate pulp. Entire independence would on the basis of 1922 consumption require 773,000 cords of these pines in addition to what we now cut, with an increase hereafter of 110,000 cords a year, the rate at which requirements have been growing since 1914.

So far soda pulp alone accepts such hardwood species as aspen, basswood, the southern gums, yellow poplar, soft maple, and others of similar pulping properties. In all the paper consumed the requirements for soda pulp in 1922 were only 759,000 cords. For soda pulp, entire independence and the absorption of pulp-wood imports are little different. The former would take, on a 1922 basis, 196,000 cords of any one or more of a number of hardwoods, with a subsequent increase of only about 23,000 cords a year, the rate of increase since 1899.

The spruce-fir-hemlock group of softwood species are now used almost exclusively for both mechanical and sulphite pulp. The use of jack pine for

sulphite pulp is still in its infancy. Mechanical and sulphite pulp together (Table 14) absorbed nearly 7,170,000<sup>7</sup> cords, or 78 per cent of the total pulp-wood requirements for 1922. Our pulp-wood requirements for these two pulp grades

**PULPWOOD REQUIRED TO MEET THE AMERICAN PAPER CONSUMPTION IN 1922  
BY GROUPS OF SPECIES**

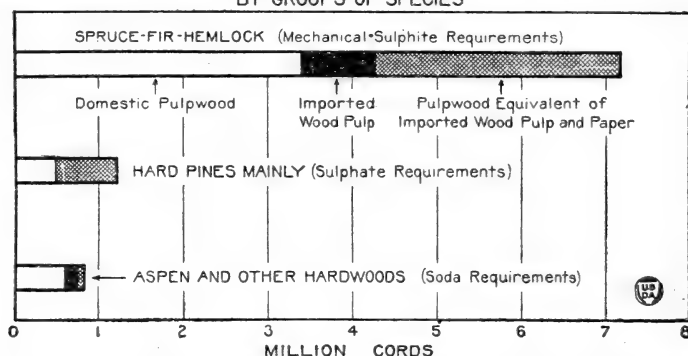

FIG. 19.—Pulp wood for mechanical and sulphite pulp constituted 78 per cent of the total required in the paper consumed in the United States in 1922. Use is confined almost exclusively to spruce, fir, and hemlock, of which there remain only limited supplies in the regions where the pulp industry is concentrated. Much smaller amounts of pine and hardwoods are needed for sulphate and soda pulp. The outstanding problem is, therefore, to secure additional domestic supplies of spruce, fir, and hemlock.

have increased at the rate of 237,000 cords a year since 1899 against a rate of about 313,000 cords a year (Table 29) for our total pulp-wood requirements. The great need under present pulp and paper processes is therefore for spruce, fir, and hemlock. To offset pulp-wood imports, it will be necessary to find about

**AVERAGE ANNUAL INCREASE IN PULPWOOD REQUIREMENTS  
BY GROUPS OF SPECIES 1899-1922**

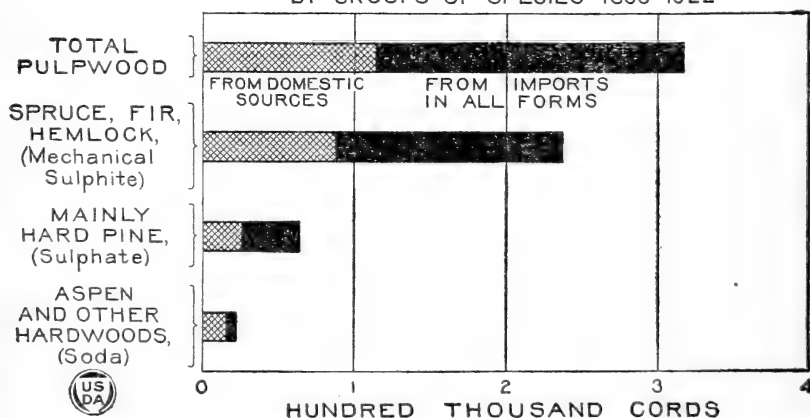

FIG. 20.—Seventy-five per cent of the average annual increase in pulp-wood requirements since 1899 has been for spruce, fir, and hemlock for mechanical and sulphite pulp. Except in hardwoods, imports of paper, pulp, and pulp wood combined have increased more rapidly than the cut of domestic wood.

870,000 cords. To be entirely self-supporting this amount would have to be increased to 3,916,000 cords, and it would be necessary to supplement the latter by an additional 237,000 cords a year to remain independent.

<sup>7</sup> This does not include the spruce, fir, and hemlock used in the sulphate process, but the omission is partly offset by the volume of species primarily suited for sulphate pulp which are used for mechanical and sulphite.

In the briefest possible terms, the urgent problem of the immediate future is to find 870,000 cords of spruce, fir, and hemlock and 180,000 cords of aspen or other hardwoods to offset pulp-wood imports.

An important but less urgent problem of the future is to secure from our own forests sufficient additional pulp wood to cover current imports of pulp and paper and to become entirely self-supporting in pulp-wood supplies. This can be accomplished by adding a total of 3,916,000 cords to the spruce-fir-hemlock cut, 773,000 cords to the pine cut, and 196,000 cords to the hardwood cut.

A third important future problem is to provide the pulp wood necessary to meet the increase in our paper requirements. This on the basis of the past decade or two would mean an annually enlarged cut of 237,000 cords of spruce, fir, and hemlock, 110,000 cords of pine, and 23,000 cords of hardwoods. The formulation of plans for future pulp-wood supplies requires a more detailed consideration, however, and this is given in the following section.

Figures 19 and 20 represent these problems graphically, and Table 29 shows additional details unnecessary to discuss.

### PROBABLE FUTURE REQUIREMENTS.

Plans to furnish pulp-wood timber in the future must rest upon probable future requirements for paper and upon the part of the requirements which are likely to depend upon wood as the raw material and the part which will come from other raw materials.

### PROBABLE FUTURE PAPER REQUIREMENTS.

Any forecast of paper requirements must be more or less speculative. Regardless of the obvious objections, however, some basis of this character is essential as a starting point in plans for supplying the necessary raw material. One of the methods which may be followed as a basis for a sane forecast is an extension into the future of the trends of the immediate past. A consideration of all grades of paper together is more likely to be correct than of each grade separately because of compensation of possible changes affecting individual grades. A curve indicating trends in paper consumption since 1810 is extended as far as 1950 in Figure 21, with some allowance for a decreased rate of increase over that of the immediate past. Available grade consumption data are also shown.

The enormous present consumption of paper makes it difficult to accept consumption in 1950 as great as  $13\frac{1}{2}$  million tons, the volume indicated in the curve. But a similar question might have been raised with justice in 1909, when requirements were greater than those of any previous year and when a prediction of the doubling of consumption by 1922 would have seemed rash indeed. The total had, however, nearly doubled in 13 years and in some grades had nearly trebled. The doubling of consumption in the past 13 years and quadrupling since 1899 makes less incredible an assumption that it may possibly double again during the next 25. But a check of the forecast of probable growth of consumption afforded by projecting the curve is possible, through an analysis of the reasons for the past increase and a consideration of their probable future influence.

Other things being equal, growth in population would in itself mean a proportionate increase in requirements. The present population of the United States is approximately 110 million. By 1950, according to the best authorities, our population should approximate 150 million. If the per capita consumption remains stationary, this would mean an increase in requirements by 1950 to about  $11\frac{1}{4}$  million tons.

## CONSUMPTION OF PAPER IN THE UNITED STATES

MILLION

TONS

2,000

lbs

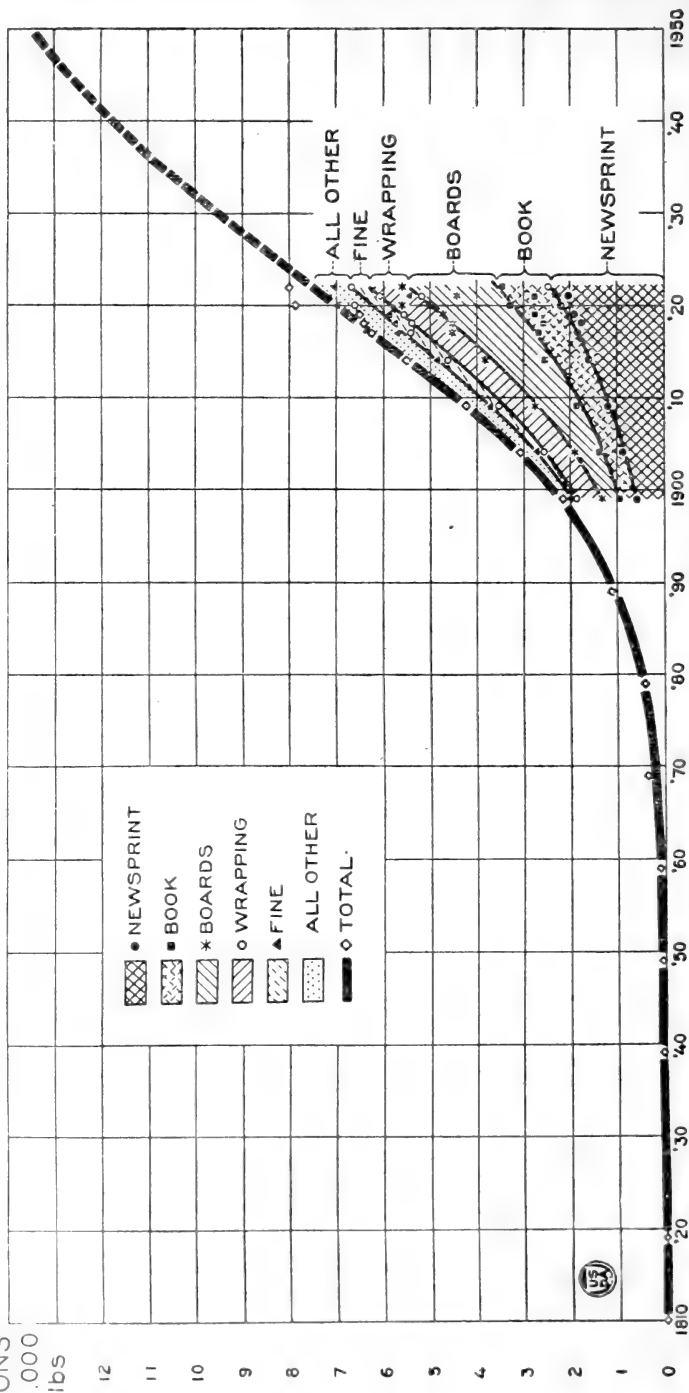

Fig. 21.—During the entire period prior to 1860, before the use of wood, paper consumption in the United States had increased only to 301,000 tons. Since that time consumption based chiefly on paper from wood has increased to 8 million tons. A smaller rate of increase than that of the last two decades would bring consumption in 1950 to 13½ million tons. Paper consumption by grades is shown by cumulative curves.

But during the last half century particularly per capita as well as total paper consumption has advanced rapidly. Between 1899 and 1922 per capita consumption increased 90 pounds, from about 57 to almost 147. An equal per capita increase during the next 25 years would with the predicted growth in population involve a total paper consumption of around 18 million tons.

Some per capita increase is likely, and a considerable increase is possible. High prices due to pulp-wood shortage may play a part in limiting that increase; but they may not play a large part, for reasons that will be brought out later. The increase since 1899 has been in the face of an almost fivefold increase of pulp-wood prices. (Table 41.) Expanding per capita consumption has been brought about partly by the great increase in the quantity of paper used for books, magazines, and newspapers, partly by an even greater increase in the quantity used industrially, in the products classified in Table 3 as "boards," "wrapping," and "all others." Practically half of the 1922 paper consumption was of these classes, with newsprint, book, and fine papers making up the other half. The same causes that during the last 25 years have been pushing upward the quantity of paper used in both fields will continue to have some effect.

A forecast of future trends in per capita consumption calls for separate consideration of each field. Density of population ordinarily stimulates per capita consumption of paper, largely because of the greatly increased volume of printed matter. Advertising accounts for much of this; and although producers and merchants are finding out better how to advertise, signs are not altogether wanting of a popular reaction against the present volume. Publishers are constantly seeking new readers and education is tending to make more. All things considered, the saturation point in consumption of printed matter still seems to be in the future but just how far it is impossible to predict with certainty.

The probability of expanded use of other and possibly new paper grades presents other considerations. The limitations of wood fiber as an industrial material are unknown. Already a pronounced beginning has been made in the substitution of various fiber boards for lumber. The use of paper and board containers of various kinds since 1900 has shown an astonishing growth. Increasing scarcity and cost of lumber may be an important factor in developing new forms of use of a material that can be produced from woods and mill waste, forest thinnings, and quickly grown small stock. Invention has certainly not yet exhausted the possibilities of pulp. A more highly organized industrial life and economic development that will raise the average standard of comfort are also factors that will tend to increase per capita paper consumption.

The possibility that other factors, which can not now be definitely foreseen, will work toward decreased consumption should by no means be overlooked. At some future time, as a result of a combination of causes, the paper consumption curve will flatten out or even reach a peak and decline. Although the former is probable, just which of the two it will be, and when, no one can predict with certainty.

The United States in 1920 manufactured more than half of the world's paper and consumed 98 per cent of that manufactured. To supplement domestic material we purchased from Canada 31 per cent of her pulp-wood cut, and nearly 32 per cent of her pulp output, about one-tenth of Sweden's pulp production, and smaller amounts of pulp from a number of other countries. We purchased also large amounts of foreign paper, the chief item being nearly 78 per cent of Canada's newsprint output. Altogether in 1920 we used 56 per cent of the world's paper. The United States constitutes to-day, and has constituted for 50 years, far and away the world's greatest paper market. (Fig. 22.) In this respect even the most progressive European countries are very poor competitors.

Germany, which is second to the United States in consumption, uses only 20 per cent of what we now require. British per capita consumption is only half of ours, and all other countries fall still further below, as indicated by Figure 23. Even though the extension of the consumption curve in Figure 21 proves to be

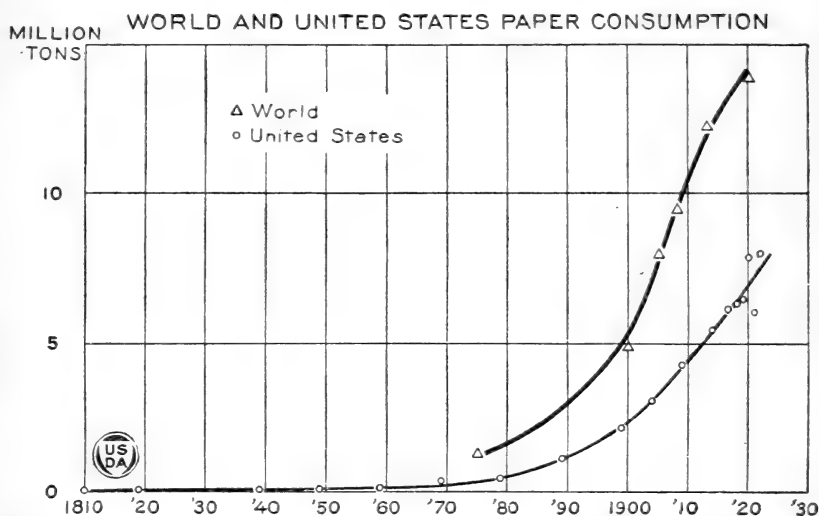

FIG. 22.—The United States is now and has since 1875 been the world's greatest paper market. American consumption in 1920 was 56 per cent of that of the entire world.

in excess of future needs, there is no reason to believe that the United States will not continue for many years to be the world's great paper market. This must be kept clearly in mind in the development of plans to insure future supplies of raw materials. A per capita increase only half that of the last 25 years, with a

**PER CAPITA CONSUMPTION OF ALL PAPER IN VARIOUS COUNTRIES—1920**

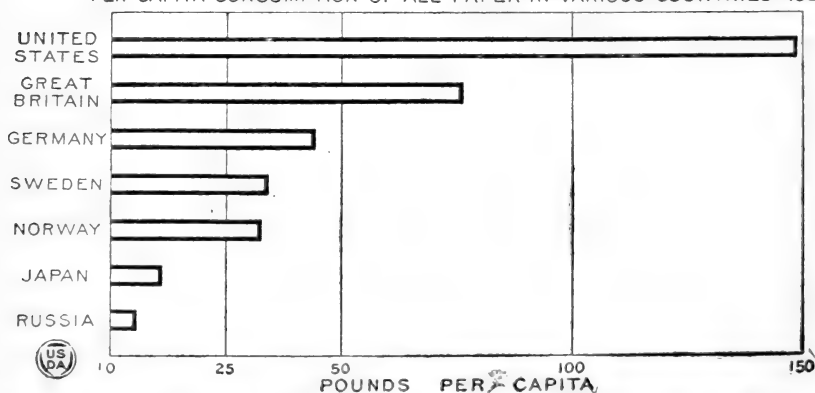

FIG. 23.—Per capita consumption of paper in the United States is twice that of Great Britain, which in turn leads the other countries shown.

population of 150 million, would bring our paper consumption by 1950 to nearly 15 million tons. Plans for future pulp-wood supplies can hardly be made with safety on the basis of paper requirements less than the  $13\frac{1}{4}$  million tons shown in Figure 21.

**RAW PULP MATERIALS OTHER THAN WOOD.**

All plants are potential pulp and paper materials, and a widespread belief still clings that the solution of the paper problem is through the use of other forms of plant growth than wood. Wood is a newcomer in the pulp world. The entire history of pulp and paper making is the story of a search, still continuing, for new and more satisfactory materials. Hardly a day but witnesses the discovery, or more often rediscovery of some new paper-making material. Recent history is covered in a preceding section and need not be repeated. The resultant to date of the competition between wood and other materials, a competition in which properties, availability, costs, and other factors have come into play, is expressed in Figure 1, where wood is shown to be far in the lead of all other materials combined. If, therefore, the present is any indication of the future, wood will continue to be the dominant pulp and paper material.

Among the reasons why materials other than wood have not proved successful for large-scale use the most important are the high cost of assemblage, transportation to the mill and storage, and the fact that many are seasonal crops with comparatively low yields per unit of pulping chemical. In the case of wood the growth of decades can be harvested in a single crop. Furthermore, the paper industry has become so accustomed to handling wood-pulp papers that pulp and paper from other materials are not accepted readily. Each reacts differently under pulping processes and the final product is slightly different and requires special manipulation in handling or printing. These factors have relegated the use of other materials than wood almost entirely to special-purpose papers, many of them of great economic value. The more promising of the materials now known warrant more detailed consideration.

Linen and high-grade cotton rags make a strong, flexible product which is the standard for high-grade book and writing papers. Very little paper even of these high grades is, however, made entirely of rags; wood pulp is usually added, forming as a general average much more than half of the pulp material used. Low-grade rags are largely used in building felts and sheathing papers, where bulk and absorption qualities are necessary. Manila stock, including both rope and jute threads and waste, are used in the strong, porous papers which are so satisfactory as containers for products like cement.

For linen, the best rag stock for paper, the United States is largely dependent upon foreign countries. Demand and hence the price of linen rags is high, both in Europe and the United States; consequently their use is confined solely to very high-grade papers where low cost is not so essential. This automatically restricts use.

Considerable use has been made of cotton rags, but here cost is important, and an active demand immediately advances price.

Straw is now restricted almost entirely to corrugated boards, to which it alone imparts the requisite properties. Straw was once used for printing paper but it has long since yielded this place to wood. Tremendous quantities of straw are available for paper manufacture in the United States, but it is available in relatively small units and present use is confined almost solely to the cereal-producing regions. Straw is bulky and has been costly in comparison with wood. Cost alone has so far eliminated it as a serious competitor for the general manufacture of paper.

Cotton linters have since the war been used to some extent in writing and book papers. This use has been made to supplement the rag supply rather than to compete with wood pulp. Although cotton-linter pulp is made from a waste product, the costs of production are usually above those of a similar pulp made

of wood. Furthermore, paper made from cotton-linter pulp is slightly different in texture and reaction and requires different treatment in manufacture.

The use of bagasse, which is the waste from cane-sugar mills, is relatively recent and is confined chiefly to the manufacture of heavy boards. Many materials, such as kelp, cornstalks, the fibrous waste from other industries, a long list of different plants, and the soft and fibrous minerals, have been tried for paper, but practically all have been rejected, at least for large-scale production. Cost primarily and products differing slightly or greatly in character from those already in use have been responsible.

The use of the nonwood-pulp materials has increased slowly; that of wood very rapidly, in spite of the constantly rising price of pulp wood, at times to levels seemingly prohibitive. The high price of pulp wood of 1920, which in many cases exceeded \$30 per cord, still proved to be below the limit which would allow other materials to compete in large quantities. Timber can be grown in large volume, in several regions, for much less than this. Any great use of materials other than wood except for special products or in regions where wood is difficult to obtain and extremely high priced seems improbable in the light of past experience and present knowledge.

### PROBABLE FUTURE PULP-WOOD REQUIREMENTS.

Since we shall, in the future, probably have to depend chiefly upon pulp wood as the raw material for paper, it is hardly conceivable that without the most drastic economies we shall ever need less than the present requirements of 9,148,000 cords. At the other extreme, if present conversion factors still hold, a paper consumption in 1950 of  $13\frac{1}{2}$  million tons, as indicated by Figure 21, would probably mean in the neighborhood of 15 or 16 million cords of pulp wood. The total would be materially influenced by such factors as the increased or decreased use of waste paper, almost certainly the former, and the higher pulp yields which may be secured through improvement of the chemical processes. Utilization of logging and sawmill waste would reduce the demand upon the forest correspondingly.

While 15 million cords may be an excessive estimate for as early a date as 1950, it is not too large a total on which to base plans for future forest growth. If requirements have not reached 15 million cords by 1950, it is likely that they will thereafter. Any part of it which may not be needed for pulp will certainly be in demand for other products.

Fifteen million cords is, therefore, taken as a reasonable annual production to which we should attempt to bring our pulp-wood supplies within the next two or three decades. If present ratios of utilization continue, nearly 12 million cords of the total would need to be of spruce, fir, and hemlock, 2 million cords of pine, and a little more than 1 million cords of various hardwoods.

There still remains the problem created by the concentration of the industry in limited regions where for many years the timber supplies have been cut so heavily for lumber, and more recently for pulp wood, that they are now much reduced. But the discussion of this phase is so involved in the possibility and ways and means of solution of the entire problem that it is incorporated in the succeeding section.

## HOW WE CAN SUPPLY PRESENT AND FUTURE PULP-WOOD REQUIREMENTS.

### PRESENT TIMBER RESOURCES, DRAIN, AND REPLACEMENT.

Important factors which require first consideration in the pulp-wood problem of the immediate future, and hardly less in that of the more distant future, are the existing timber resources of the country as a whole, the rate at which they are being used for pulp wood and all other purposes and the additional drain caused by fire and disease, and the extent to which the total drain is offset by new growth. The crucial function of the existing resource is to bridge over the period from the present to the time our forest lands can be made fully productive by forest management. A consideration of the resources of the United States as a whole will accordingly serve as a background for a necessary and more detailed consideration by regions, and in some cases by States.

The pulp and paper industry is full of rumors and suggestions of modified and entirely new pulping processes which it is claimed will make the accepted pulp species available for more general use or even bring entirely new species into the pulp group. It is obviously possible that at almost any time the commercial feasibility of one or more of these processes may be demonstrated and that thereby our conception of pulp-wood resources may be revolutionized. Until so proved, however, all new or modified processes must remain speculative to a greater or less extent, and it will be necessary to base this national, regional and State survey primarily on established usage. The tendency in pulp and paper making, as in all other forms of wood utilization is, however, toward a gradual enlargement of the number of species regarded as suitable, and it would be surprising if in the future, with an increasing timber shortage and with almost world-wide research into pulp and paper-making materials and processes, this tendency was not hastened. The stand of species not now used for pulp and paper making is therefore of more than academic interest, along with the stand of those already in demand.

Less than a third of the original timber stand of the United States remains. Of saw timber, the form in which countrywide estimates have hitherto been considered, we now have approximately 2,200 billion feet, board measure, of virgin and second growth in the United States proper, and an additional 80 billion feet in southern and southeastern Alaska. (Table 44.) Including material below saw-timber size we have more than 3,500 million cords of species now used for pulp and paper, about 55 per cent of the total stand. A much larger proportion of the species and hence of the volume of Alaskan timber is suitable for pulp, and the total is only a little short of 170 million cords.

Of the total stand in the United States about 760 million cords, including jack pine, is suitable for sulphite and mechanical pulp, for which it will be remembered 78 per cent of the wood pulp utilized is now required. Eight hundred fifty million cords are suitable for soda pulp, which now absorbs 8 per cent of our requirements, and the very much larger total of 1,920 million cords is suitable for sulphate, which takes 14 per cent of the total pulp wood needed. (Table 45.) All of the Alaskan pulp species fall within the sulphite-mechanical group.

These totals make the annual pulp wood cut from American forests of  $4\frac{1}{2}$  million cords, the consumption of pulp wood by American mills of approximately 1 million cords additional, and even the total amount of pulp wood required for all the paper we consume, look exceedingly small. The remaining timber must, however, meet the requirements for a large number of other important forest products, such as lumber, fuel wood, ties, etc. The annual pulp

wood cut from American forests, although second to no product in economic importance, is now less than 2.5 per cent of the total volume cut for all purposes or destroyed. To supply all of our present requirements and to be entirely independent in pulp wood, pulp, and paper would require less than 5 per cent of the amount of timber now annually cut or destroyed. (Table 48.)

The total annual drain upon American forests exclusive of Alaska falls only a little short of 25 billion cubic feet. While this approximates one-thirtieth of the total visible wood supply of the United States, annual replacement through new growth reaches only one-fourth of the drain, or 6 billion cubic feet. Our timber resource is therefore becoming less by nearly 19 billion cubic feet, or 160 million cords a year.

The general outlook might not be so serious if the cut and destruction were confined mainly to timber of the larger sizes. Unfortunately, however, in the timber below saw-timber size drain exceeds renewal by about three times, so that the possibility of replacing the larger-sized timber is rapidly being reduced. The drain upon the larger-sized material suitable for saw timber is still more excessive, reaching five and one-half times the annual growth.

No other interpretation of these and other known facts is possible than a serious future timber shortage, already in fact beginning for many important products. Data are not available for any very satisfactory comparison of stand, current drain, and growth for all the pulp-wood species taken together, but there is little reason to hope that the situation is much better than for the timber stand as a whole. While a timber shortage will in general be felt first in the high-grade products, such as lumber, an inadequate supply of timber means of course sharper competition among forest industries for the remaining material and higher prices.

In that competition the pulp and paper industry has great advantages. It can use small-sized trees, and it can under the conditions that have hitherto obtained outbid the lumber industry, its chief competitor, for at least the lower grades of saw-log material of the species most in demand by both. The bid of the lumber industry for such stumpage has gone up as regional timber supplies have been cut, but its limit is reached when it becomes cheaper to meet requirements by lumber from other regions. The longer the freight haul from the regions of virgin forests and the greater the stumpage values in those forests, the higher the competitive bid that the pulp and paper industry must be prepared to meet in the older regions. In short, a timber shortage will affect pulp-wood supplies, which will be higher in price and more difficult to get, even though requirements for pulp wood are small in comparison with requirements for other purposes and with our total timber supplies.

Depletion of timber supplies is also bringing an increase in the value of timber below saw-log size and is certain to carry that increase further. In various parts of the East conditions have already reached the point at which the practice of forestry by private owners is good business. As the "expectation value" of young growth is recognized, the competition of the lumber and other forest industries for raw material will more and more make itself felt in the form of higher values placed upon immature timber and in an unwillingness on the part of forest owners to permit cutting of their stands except under the practice of forestry.

This will undoubtedly not be wholly to the disadvantage of the pulp and paper industry in the long run, though at first it may come decidedly as a blessing in disguise. The application of forestry will in time make available for pulp a great amount of small-sized material which should be cut out of growing stands to secure maximum production. Eventually, it is safe to predict, economic conditions will produce a radical change in the character of the pulp and paper indus-

try as related to the forest. Compelled to adjust itself to sustained supplies in place of timber mining, it will attain permanence by supplying its needs either through pulp-wood production as an incident or supplement to the growing of timber for other requirements, or through intensive production of pulp wood solely, on short rotations, under the principles of forestry. Doubtless during the transition period at least self-preservation will require it to resort to both.

This, however, concerns the future rather than the immediate timber situation, already summarized. That situation presents a broad and urgent national problem. On top of it we now face the advisability of an increased cut from our own forest lands to offset present pulp-wood imports, to meet the rapidly increasing demands of the future, and in general to reduce the extent of our dependence upon foreign timber. This is a handicap which must be overcome.

A detailed examination of the widely different conditions in each of the several forest regions offers the only possibility of working out a plan for an increased pulp-wood cut in the immediate future which will not make the general timber situation still worse than it is. Before that is attempted, however, the national aspects of another and closely related resource, the area of forest land and the extent to which it is now being reduced, must be taken into account. Although anticipating a phase of the question which might logically be considered later, the more recent trends affecting the forest-land area are also projected into the future in order to establish an area basis for the determination of potential timber growth under forest management.

### PRESENT AND PROBABLE FUTURE AREA OF FOREST LAND.

The area of forest land in the United States has been reduced from its original extent of about 822 million acres to approximately 470 million. After three centuries of continuous struggle the area of improved agricultural lands has grown to 503 million acres, only slightly larger than the residue of forest land.

It has become increasingly evident, particularly during the last four or five decades, that there are very definite limitations to the further encroachment of agriculture upon forest lands. Decades of repeated attempts in the various forest regions have shown that a large part of their land area can not be put to profitable agricultural use. Agricultural economists have been gradually coming to the conclusion that the future tendency in agriculture will be more toward intensive cultivation of the better-lands, and that those upon which the margin of profit is small or uncertain, because of poor soil, or climate, or topography, or location, will tend to pass out of agricultural use. In some of our forest regions, in fact, this tendency has been under way for many years, and in many the reversion to forest is proceeding faster than the cultivation of new lands. For the whole United States there has grown up during the past 50 years an area of scores of millions of acres of cut or burned-over forest land which has not been brought into farms, in spite, until very recently, of the greatest popular demand for land in our entire history.

Whether land of relatively low agricultural value has gone into agricultural use up to the present has depended in general upon the ability of the farmer to make a living on it from the production of farm products. In the determination of future land use the possibility of greater profits from timber growing will undoubtedly be a factor. Unquestionably there will be a shifting of forest land into agricultural use in some regions and localities, and the opposite tendency in others. A rough classification of the area under each form of use is gradually being determined by the play of economic forces. The future area of forest land may be slightly less or more than our present area of 470 million acres. Some agricultural economists believe that with higher production and somewhat

modified food requirements a somewhat larger area may be devoted to the growing of timber with full justice to the food requirements of our future population. They are strengthened in this belief by present conditions in the agricultural industry, in which in general the marginal lands are hardest hit. Four hundred seventy million acres may, however, be taken as a fairly close approximation of the area which will probably remain as forest land.

This total does not include the forest lands of Alaska. While there are many millions of acres in interior Alaska a large part of which will unquestionably remain forest land, this report deals only with the forest lands now included in the Tongass and the Chugach National Forests in southeastern and southern Alaska, respectively. For those 5 million acres of forest lands may be added.

Another important factor in the production of pulp wood and of other timber products is the distribution of forest lands in relation to population, and hence to wood requirements. Except for the treeless plains between the Mississippi and the Rocky Mountains the forest-land area is widely distributed. Seventy-five per cent of the total lies east of the Great Plains, in the territory which contains practically all of the larger cities and 79 per cent of our total population. Paper consumption increases with density of population, so that the East is now and will long continue to be the chief area of paper consumption.

Our forest-land resource is still enormous in extent therefore, well distributed in accordance with population, and likely in the future to be at least equal to that of the present. One hundred and thirty-eight million acres is still covered with virgin timber, 250 million with volunteer second growth, and 81 million, devastated by logging and fire, lacks largely or altogether forest growth of any kind.

### HOW WE CAN SUPPLY REGIONAL PULP-WOOD REQUIREMENTS.

The preceding discussion of national land and timber resources paves the way for a more detailed regional examination of pulp-wood possibilities. For a complete and satisfactory understanding and for specific answers to all pertinent questions the following data would be absolutely essential:

(1) The size, character, and volume of the present timber stand, by species, and by States and regions.

(2) The present drain, by species, States, and regions, the total drain, and separately the cut for different purposes; and losses from fire, insects, fungous diseases, and windfall.

(3) Forest areas, by types and States.

(4) The present growth, by species and forest types; and by States and regions; its character and rate.

(5) Similarly, potential growth under forest management of varying intensity.

Such ideal data are available for no one region, and much of it is unavailable for any region. The information outlined could be secured by no other means than an exhaustive timber survey such as has never been attempted. Lacking the results of a survey, the discussion is limited correspondingly, and for much of what is given no positive claim can be made of accuracy in detail. The general conclusions reached, however, are believed to be substantially correct.

#### MIDDLE ATLANTIC STATES.<sup>5</sup>

The pulp mills of New York in 1920 manufactured nearly 60 per cent of the total spruce-pulp-wood imports from Canada, and nearly 50 per cent of that of aspen. Pennsylvania mills purchased nearly 13 per cent and 20 per cent, respectively, of the imports of the same species. Since 73 per cent of the spruce-

<sup>5</sup> The grouping of the States is that followed in the report on Senate Resolution 311 and is shown in Figure 24.

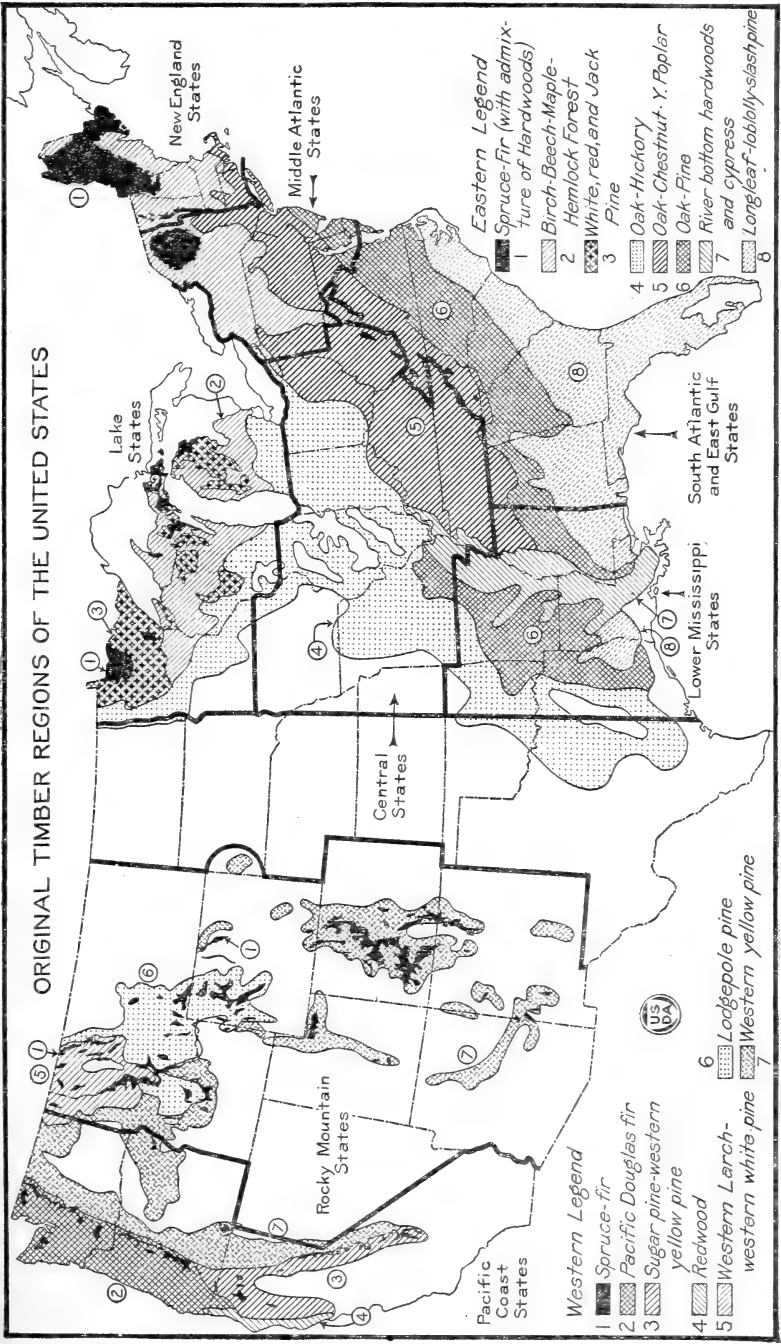

Fig. 24.—The original forest area of the United States was approximately 822 million acres, distributed as shown. Four hundred and seventy million acres remain in forest land, and approximately this area may be counted on for future forest growth. The boundaries of the State groups discussed in this report are outlined in heavy black lines

pulp-wood import problem and 69 per cent of the aspen problem, on the basis of 1920 data, centers in two Middle Atlantic States alone, the first and most critical problem is to determine what provision, if any, can be made in these States to offset these imports. What is to be done for the permanent support of pulp and paper manufacture promises to be almost equally important. The graphic representation of the distribution of the spruce imports in Figure 25, and of the aspen imports in Figure 26 emphasizes still more strikingly the concentration of the problem in the Middle Atlantic States.

#### NEW YORK.

New York leads all other States in the production of paper. It ranks second in the production of wood pulp and third in the consumption of pulp wood. It produces a very large amount of mechanical and sulphite pulps, and a correspondingly large amount of newsprint paper. Soda-pulp production is much smaller.

The outstanding fact in the present New York situation as to the timber supplies and pulp-wood requirements is the very large and rapidly growing spruce-fir pulp-wood imports from Canada. As recently as 1906 New York imported less than 40 per cent of the spruce utilized in its mills, while in 1920 spruce imports had risen to 59 per cent of consumption. The very large part of the total pulp-wood imports taken by New York has already been stated.

The present stand of spruce and fir in New York, as shown by Table 50, is relatively small, reaching altogether only about 14 million cords. Of this approximately 7 million is on the State preserve, on which cutting is prohibited by the State constitution. Some of the spruce and fir lands are held by lumber companies and as private estates for recreation. The holdings of the pulp and paper companies aggregate about one-seventh of the total spruce-fir stand in the Adirondack region. It is reported that but three or four companies have holdings sufficiently large to carry them 10 years without purchases of additional supplies, and that only one company has a supply for 20 years.

A rather detailed study of the New York situation along the lines of the preceding paragraph indicates that probably less than half of the total spruce-fir stand is now available for pulp and paper manufacture, a total of approximately 6½ million cords. This stand, according to 1920 figures, is being cut at the rate of about 400,000 cords a year for pulp wood, and would prove even more inadequate should it be compelled to supply any or all of the 545,000 cords (1920) additional now imported from Canada. The cut for lumber in 1920 reached an equivalent of 57,500 cords. No data are available to show the cut for other purposes, or the losses by fungous diseases, insects, and fire. The total drain on this forest, which is therefore unknown, is being offset by growth in the spruce-fir type of the Middle Atlantic States, which is confined to New York, of about 300,000 cords per year (Table 49); but because of State and other holdings only about one-half may be available for pulp wood.

Such incomplete and unsatisfactory data as exist are sufficient to show conclusively that the situation is growing rapidly worse rather than better. The many New York mills which are without timber holdings of their own are most directly concerned. Practically all the rest, however, find it necessary to supplement their own inadequate holdings by purchases of pulp wood. Any increase in the cut to offset pulp-wood imports would merely draw more heavily upon the already depleted stands of the State. It would intensify still further the competition between the pulp mills and other forms of use. Imports might be offset in part through increased purchases from Vermont, which, as shown later, might be able to supply its own mills if timber is not diverted outside of the State.

For some mills, or for modified processes, water shipments of pine and hardwoods from the South might be made.

Hemlock, with a total stand in New York about the same as spruce and fir, is so widely scattered and so largely held and under manufacture by lumber companies that the pulp and paper industry has little opportunity to stave off the inevitable by shifting its requirements.

To bring the spruce-fir lands into maximum timber growth under forest management is a question of years, while the necessity of meeting current demands of the immediate future is in the worst cases a matter of months. Without radical changes in the pulping processes, of a character to be discussed later, which would make such species as beech, birch, and maple generally available for other pulps than soda, the gradual exhaustion of local supplies, regardless of any other factors, can therefore mean only one of two things for some, at least, and possibly many of the sulphite and mechanical mills—the manufacture of other materials than pulp, or closing down.

Forestry measures already adopted are good as far as they go. The efficiency of fire protection, under the stimulus of timber scarcity and high stumpage prices and of State and Federal cooperation, is gradually improving. Some stands in the past have been cut to a fixed diameter limit, but other cultural operations and replanting of waste lands to secure full production are still almost entirely in the future.

On the basis of the best data available, it is believed that ultimately under intensive forest management production on the entire acreage of the spruce-fir type in New York could be brought to 920,000 cords, which is practically enough to support permanently the full requirements of the existing industry if all were available. Possibly it could be supplemented enough from hemlock to offset the diversion of spruce and fir to other purposes. Long before that time, however, the wide use of other species by modified processes seems to be the only means of retaining a substantial part of the present development. Otherwise the output of the mills which will pass out of existence must be made up by greater production in the other regions of the United States.

Aspen, with an 85,000-cord pulp-wood import (1920) and a cut from within the State of less than one-third this amount, seems from the unsatisfactory data available to be as seriously jeopardized as a source of supplies for soda pulp as is spruce for sulphite and mechanical. Manufacture could if necessary, however, be diverted to birch, beech, and maple, less desirable but still satisfactory, of which a stand still remains probably large enough to meet requirements until forest management could become fully effective.

#### PENNSYLVANIA.

Pennsylvania was in 1920 fourth among the States in the consumption of pulp wood. It was first in the production of soda pulp, and ranks high in the manufacture of book paper. It has in common with the New York industry a dependence upon spruce-fir forests for sulphite pulp. Data on which to base specific statements of timber supplies of various species, and the part of the supplies available for pulp and paper manufacture, are very meager and unsatisfactory. Such as warrant specific statement are incorporated in Table 51. It is most significant, however, that of the 17 pulp mills now operating in Pennsylvania only one secures its timber entirely from the State, and all but two others import all of their wood requirements. Seventy-four per cent of the pulp wood used by the mills of the State comes from outside, 45 per cent from Ontario and Quebec, and the rest from West Virginia, Maryland, Virginia, North Carolina, and Michigan. One Pennsylvania company is even relogging old hemlock operations for dead tops, stumps, and old logs. Eighty-five per cent of the 143,000

cords of spruce used in 1920 came from Canada, and 69 per cent of the 53,000 cords of aspen. The combined holdings of the pulp and paper companies in the State are approximately 90,000 acres, practically all owned by one company.

It would seem that the large acreage of forest land within the State bearing in mixture the trees suitable for the soda process should fully meet the State requirements, but for these woods the pulp and paper industry meets severe competition from a very large and active coal-mining industry and from hardwood distillation plants. While, therefore, the soda-pulp industry is in a bad way for supplies, it is not so seriously situated as the sulphite mills.

As it becomes more and more difficult to secure spruce, fir, and hemlock pulp wood, the requirements of the sulphite mills may in part be shifted to other species, for example, to southern pines from outside the State. This under present processes would be possible only for a limited number of mills manu-

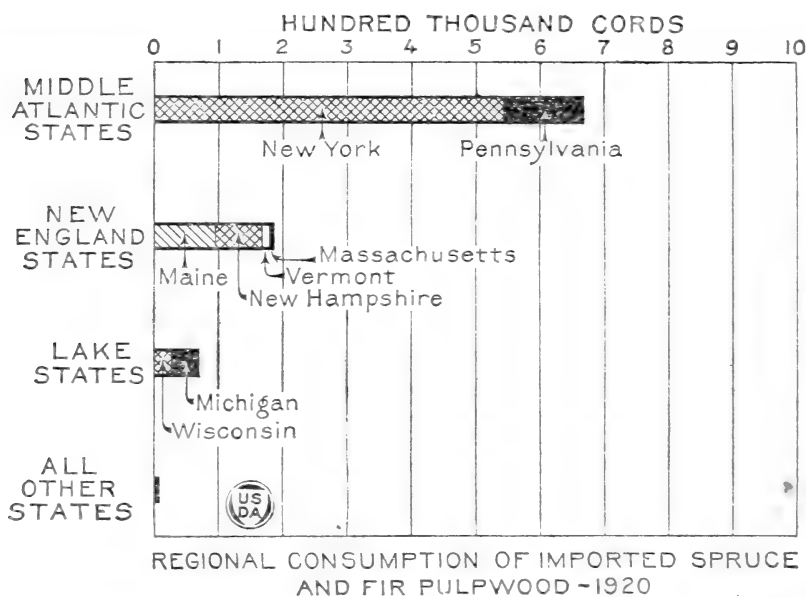

FIG. 25.—The Middle Atlantic States used 73 per cent of the Canadian spruce and fir pulp wood consumed in the United States in 1920, and here the stoppage of pulp-wood imports would hit the hardest.

facturing special products. Sulphite mills might in part be shifted to the soda process, but they would also have to import much of their material from other States. Pulp mills might even in some cases have to shift to other kinds of manufacture as an alternative to closing down altogether. The situation may work out along almost any if not all of these different lines.

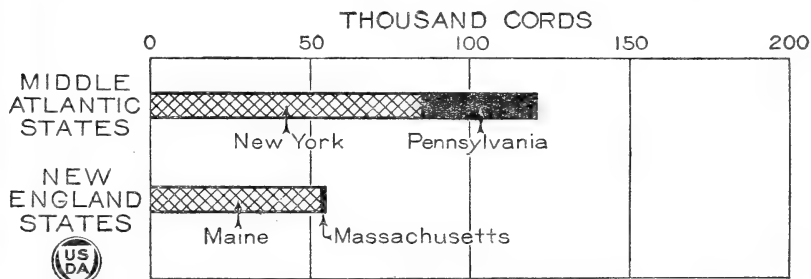

Possibly timber growth under intensive forest management on the highly productive forest lands of Pennsylvania would be very great and would include a large but unknown volume of species suitable for soda pulp, and possibly the hemlock needed to support at least a part of the existing sulphite industry. Under intensive forestry there would also be the possibility of imports of southern pine more than ample to meet all present and probably future requirements of the mills which could use it. This will be covered in more detail in the discussion of the Southern States.

The industries in the other Middle Atlantic States—New Jersey, Delaware and Maryland—are relatively small and need not be discussed in detail.

It is clearly apparent, however, that the situation in both New York and Pennsylvania is extremely critical. The gradual exhaustion of local supplies, regardless of any other developments, promises to make the future situation worse rather than better. Any development which produces or accentuates a shortage of supplies will inevitably tend to stimulate the development of the industry in other parts of the United States. Local shortages might be met temporarily by modified pulping processes which would utilize other woods. The only promise in either State, however, for a permanent industry on anything approaching the present scale is through intensive forest management in the forests of pulp species, aggressively applied at the earliest possible date. The sooner and the more intensively it is applied the larger the part of the present industry it will be possible to save and maintain.

#### NEW ENGLAND STATES.

Next to the Middle Atlantic States, the New England States are most immediately and seriously concerned as to their pulp-wood supplies—Maine and New Hampshire for spruce, and Maine also for aspen. As a group, the New

#### REGIONAL CONSUMPTION OF IMPORTED ASPEN PULPWOOD 1920

FIG. 26.—The soda-pulp mills of New York and Pennsylvania used 69 per cent of all imported aspen in 1920, and are most concerned as to continued supplies. Maine mills are involved, but in less degree.

England States secured (1920) 20 per cent of the entire Canadian spruce-pulp-wood import, and about 31 per cent of the aspen. This relationship to the Middle Atlantic States is shown graphically in Figures 25 and 26. The spruce-fir forest of northern New England is the chief center of the mechanical and sulphite pulp and the newsprint paper industry in the country; Massachusetts plants are devoted primarily to book and writing paper

#### MAINE.

Maine leads all the States of the country in the production of wood pulp and consumption of pulp wood. The pulp-wood cut is  $2\frac{1}{2}$  times that of New York, but the area of spruce-fir forest in the wild lands of the State is more than 4 times as large and the volume of these species available for pulp wood is  $3\frac{1}{2}$  times as large, so that Maine has been and will in the future be in a much better position to support its present industry than New York.

Total spruce-fir stands, now probably under 45 million cords, are being drawn upon annually to meet the lumber cut and the pulp-wood consumption of the State which take about 1,470,000 cords, and to supply possibly an additional 75,000 cords of pulp wood for New Hampshire. (Table 53.) The losses from the spruce bud-worm epidemic during the past few years have been estimated at about  $27\frac{1}{2}$  million cords. The amount of loss from other insects, fungous diseases, and fire is unknown. The volume of material cut for other purposes

than lumber and pulp, while small, is also unknown. Partly offsetting these drains is the present growth of the spruce-fir type, which for all New England has been estimated at 1,060,000 cords a year. Maine contains about 85 per cent of the type. Entomologists estimate that this rate of growth has been reduced approximately one-third by the bud-worm epidemic, and will so continue for several years.

A rather detailed study indicates that only approximately  $34\frac{1}{2}$  million cords out of the total stand is available for pulp. Only 6 of the 17 timber holdings in Maine which contain more than 100,000 acres belong to pulp and paper companies. Such companies hold only about 20 per cent of the wild-land area of the State, on which the spruce and fir are almost entirely located. Excepting the large holding estates, lumber companies now hold between 12 and 18 per cent of the wild-land area, in contrast with the ownership 20 years ago of practically 100 per cent. To supplement their own holdings, pulp and paper companies depend upon Canada and upon purchases from a number of large estates, which for many years have followed a crude system of forestry in allowing the cutting of trees above a specified and progressively lowering diameter limit. This practice and the development of a more and more efficient fire protection, aided by rather unusually favorable climatic conditions, have preserved in Maine a more satisfactory timber supply and growth than in almost any other region. The stand available for pulp is being cut at the rate of about 1,020,000 cords a year for mills in the State, with additional shipments to New Hampshire. Local mills also in 1920 supplemented domestic supplies with imports of approximately 93,500 cords of spruce and fir.

These are the known facts bearing upon the present situation and the immediate future. They do not make it possible to measure either in exact terms, but are sufficiently clear to warrant the conclusion that there are too many entries on the wrong side of the ledger and that it already shows too much of a deficit.

The outlook, unless modified pulping processes can make other species available, is probably an enforced curtailment of pulp and paper production more or less gradual, dependent on developments, which will hit first and hardest the pulp mills without available timber supplies of their own. The cut of many other mills will probably be shifted in much greater degree than at present to their own inadequate holdings, with still more serious overcutting. It is very doubtful if immediate application of the most intensive forestry measures over the entire spruce-fir type of the State can produce results soon enough to prevent such a curtailment. The outlook for the immediate future, although far better than in New York or Pennsylvania, is far from bright. Ultimate future possibilities in spruce and fir production can best be considered for New England as a whole.

#### NEW HAMPSHIRE.

New Hampshire is much less favorably situated than Maine. The total stand (Table 54) of spruce and fir is probably less than  $9\frac{1}{2}$  million cords, and this is being reduced annually at the rate of about 296,000 cords by the cut for lumber and pulp wood alone, and an additional amount by fire, insect infestations, and fungous diseases. The spruce bud worm, while much less serious than in Maine, has been responsible for heavy losses. Growth can be judged only in the light of a total for the spruce type of New England of 1,060,000 cords, and the fact that 10 per cent of the type area is in New Hampshire—at best only the roughest kind of an approximation.

Spruce-fir stands available for pulp and paper manufacture probably fall under  $5\frac{1}{2}$  million cords. The pulp mills of the State consume about 300,000 cords of

American wood, of which possibly as much as 100,000 cords is secured chiefly from Maine, but some also from Vermont. They consume also about 75,000 cords from Canada. Unless relief can be secured through new pulping processes, the outlook in New Hampshire is similar to that for Maine but far more serious. The effects of shortages would inevitably be extended in part to Maine and also to Vermont. Except as indicated, curtailment of production seems the only possible outlook. The hemlock supply is relatively small, and is available to such a limited extent that it affords no hope of relieving the situation.

#### VERMONT.

Vermont offsets its exports of spruce and fir to New York and New Hampshire to the extent of about 10,000 cords, on the basis of 1920 data, by imports from Canada. The data available (Table 55) make it more or less uncertain whether the Vermont mills can continue at their present capacity, even though intensive measures of forest management are immediately put into effect on all of the spruce-fir lands. Unquestionably the margin is too small for any reasonable degree of satisfaction. Vermont, however, is in a very much better situation than New Hampshire, and probably even than Maine.

#### POTENTIAL SPRUCE GROWTH IN NEW ENGLAND.

The lumber and pulp-wood cut of spruce and fir in the three northern New England States now reaches above 2 million cords a year. Imports from Canada increase the consumption of the pulp mills by 180,000 cords of spruce and fir. The replacement by growth in the spruce-fir type, which has been estimated at 1,060,000 cords, is now temporarily reduced by the spruce bud worm and is offset still further by additional losses of unknown amounts through other insects, fire, and disease. The opportunity for large production under intensive forest management, however, is very favorable. With such management applied to the entire 10 million acres of spruce-fir lands, growth could be brought ultimately to 3,850,000 cords. (Table 52.) Not all of the timber in the spruce-fir type consists of spruce and fir. On the other hand, the beech-birch-maple type includes enough spruce and fir to balance. Future allowance must be made for probable use of spruce and fir for lumber and other purposes. But the total of 3,850,000 cords is so far above present requirements, even when supplemented by imports from Canada, that it will well justify the most intensive efforts to bring it about.

As a stimulus, there is the 1920 cost of \$26.78 per cord for imported spruce pulp wood delivered at the mill. This is unquestionably more than enough to cover the entire cost per cord of growing a crop of pulp timber. A large part of this cost grew out of the scarcity of timber, competition among purchasers for the available supplies, and high freight costs for excessive hauls. This is a sum which the pulp and paper industry might better have placed in such part as needed in timber cultural operations on American soil than in freight on Canadian wood. The total possible growth in the spruce-fir region of New England alone falls only about 650,000 cords short of the total 1922 pulp-wood cut of all species in the United States.

#### SODA PULP WOOD IN NEW ENGLAND.

No consideration has been given to the soda-pulp industry of New England. Maine mills take practically the entire Canadian export to New England, about 54,000 cords (1920) of aspen a year. This volume could possibly be supplied from the scattered aspen stands of the State if it became necessary, and there would still be the entirely feasible possibility of utilizing beech, birch, and maple

instead. Large stands of these species have usually, up to the present, been passed over, and the possibility of growth exceeds those in the spruce-fir type by approximately a million cords a year. Competition for these species for other purposes will grow, however. The mills of Massachusetts can draw upon suitable species from the oak-chestnut-yellow poplar and oak-pine types, which could supply larger quantities than at present.

The situation which must be met in New England is primarily that of increasing the growth of spruce and fir rapidly enough to prevent a serious curtailment in the more immediate future of mechanical-sulphite pulp and newsprint paper production. All of the information available indicates that, without a possible use of other species by new pulp processes, there will have to be some curtailment of production through the gradual exhaustion of domestic supplies. Such exhaustion, even though it is not aggravated by other conditions, will unquestionably tend to force the development of an industry in other parts of the United States. Increased pulp and paper production in the Northeast can only follow timber yields, brought about by intensive forest management, higher than the drain on the forest.

#### LAKE STATES.

Although the pulp-wood import problem of the Lake States is only 7 per cent of that of the entire United States, these States rank below only the New England and the Middle Atlantic States as a center of pulp and paper production. They manufactured in 1920 over 20 per cent of the wood pulp in the United States, mostly for newsprint paper, and Michigan and Wisconsin have a large production of other papers. The question of first importance, and one of the immediate future, is the possibility of making up from our own forests, if necessary, the 70,000 (1920) cords of spruce pulp-wood imports of Michigan and Wisconsin. The second problem, also one of the immediate future, is the possibility in a region with a well-developed industry of enlarging the scale of manufacture enough at least to offset a possible curtailment in the two State groups already discussed. The third problem relates to the size of the industry which can be maintained permanently in the future, and particularly whether there is the opportunity to reduce our imports of paper and pulp by means of an enlarged pulp-wood cut. These considerations place the Lake States immediately following the Middle Atlantic and New England in point of urgency.

#### MICHIGAN.

Michigan ranks fourth among the States in paper production, but confines its output almost entirely to book, other high-grade papers, and boards. The total stand of spruce and fir is estimated at 6 million cords (Table 57), half of which is fir so defective that it is a much smaller factor than its total would indicate. The total stand of the State does not make a very good showing in relation to the present lumber cut and consumption of domestic pulp wood, amounting to about 130,000 cords (1920), and further the geographical separation of the upper peninsula, which contains the great bulk of the stand, makes this timber tributary chiefly to the Wisconsin mills. The Michigan mills, most of which are on the lower peninsula, are thrown back on the small scattered spruce-fir areas in the swamps of the lower peninsula, and already secure nearly 40 per cent of their spruce and fir from Canada. With or without imports of pulp wood, the outlook of the immediate future for spruce and fir promises to be worse instead of better.

Hemlock in Michigan is used for sulphite pulp nearly as extensively as spruce. The hemlock stands, three times as large as the spruce and fir, are mostly on the upper peninsula. The lower peninsula pulp mills secure their hemlock mainly

from the upper peninsula, in competition with the Wisconsin pulp mills, from lumber companies which hold and cut most of the timber. A solution of the problem of the immediate future through the greater utilization of hemlock is not so promising as it might be.

The greatest opportunity will be a shift, already in process to the jack-pine stands, which are double those of spruce and fir, although in part so scattered as to be unavailable under present conditions, or under any that are likely to obtain in the near future. Jack pine, however, in case of need may possibly be made to carry the sulphite industry until forestry measures can insure a permanent timber supply. Even this will depend to some extent upon how serious an epidemic of jack-pine sawfly, now apparently beginning in the Lake States, proves to be, and upon the growing demand for jack pine for other purposes. Michigan mills manufacture practically no soda pulp. But there is enough aspen, basswood, beech, birch, and maple on the lower peninsula to support an industry of perhaps 50,000 to 100,000 cords a year. Possible timber production under intensive forest management will be discussed for the Lake States as a whole, the only manner in which the character of the data available justifies.

#### WISCONSIN.

Wisconsin has for many years ranked third among the States in pulp production, and now approaches New York closely. Its production is confined largely to mechanical and sulphite pulps. It ranks about third in both newsprint and total paper production.

Although only about 27,500 cords of spruce pulp wood were imported in 1920 from Canada, Wisconsin is in about as critical a condition as to available supplies within its own boundaries as any other State. The tendency among the Wisconsin mills has been to acquire only small holdings to tide over possible emergencies, and to depend upon the open pulp-wood or log market for normal supplies. The stand of spruce in the State, probably about 1 million cords, of which only a part is available for pulp wood, is so small that it could hardly supply the spruce requirements of local mills for more than two or three years if they were entirely dependent upon it. Although the total stand of fir is somewhat larger, probably still less than of spruce is available for pulp wood. The hemlock stands, while originally extensive and still amounting to more than 30 million cords, are held very largely by lumber companies, so that aside from their own timber holdings paper mills have to secure hemlock logs in competition with the sawmills. (Table 58.)

In 1920 a representative of one of the companies purchasing pulp wood for a large number of mills stated that spruce supplies for the Wisconsin mills were in 1904 secured largely in Wisconsin, and that in 1915 these mills had to bring their material from farther north, in Minnesota, but that it was rarely necessary to go more than 50 miles north of Duluth. In 1920 a material part of the supplies came from the extreme northern part of Minnesota. Spruce was being hauled in 1920 from 700 to 750 miles by rail from Minnesota to Wisconsin mills, and from 1,000 to 1,200 miles from Canada. Meanwhile, the competition of Minnesota mills, alarmed as to their own future supplies, had become so severe that Wisconsin was forced to secure its spruce in rapidly increasing quantities and at higher freights from the northern peninsula of Michigan.

Most of the spruce and fir now used comes either from Minnesota or the upper peninsula. Competition of Minnesota mills threatens gradually to eliminate that source, and the upper Michigan supply is comparatively limited. For hemlock, of which a much larger stand still remains both in Wisconsin and the upper peninsula, the mills can draw on their own small holdings in both States; to a certain extent they may be able to trade their hardwood timber for hemlock; they can as in the past purchase the poorer logs from logging operations. They

may in more severe competition take higher-grade logs in addition, and they may as heretofore purchase from farmers second-growth hemlock, exceedingly limited though it is, and thereby aid in eliminating the possibility of future hemlock stands. The heavy hemlock cut for lumber, which is nearly twice that for pulp in Wisconsin, the cut for other purposes, and losses from fire, insects, disease, and windfall, the failure of hemlock to reproduce up to the present time except in very limited quantities, and the small holdings of pulp companies, all tend to offset the seeming advantage from the size of the present stand. In spite of these handicaps the cut of hemlock can probably be increased to a greater or less extent for a relatively limited period, possibly for two decades, to offset decreasing supplies of spruce. But there is little promise of any material enlargement of the industry on the basis of hemlock supplies in the immediate future, and there seems to be no chance for a permanent enlargement.

As in Michigan, only the jack-pine remains. Wisconsin has a stand of 10 million cords, in part so scattered as to be unavailable and in part certain to be demanded for other use. This can probably be supplemented from the upper peninsula and Minnesota. Entomologists believe however that the jack-pine stands of the Lake States are threatened by an attack of the jack-pine sawfly, and this may reduce the amount available. Just what losses may result, and how they may affect future pulp-wood supplies, it is impossible to predict with certainty. The present sulphite industry can possibly, however, be maintained on hemlock and jack pine until new supplies of the pulp timbers can be grown, if the most energetic efforts to grow them are begun immediately and generally. Otherwise, barring new pulp processes, future curtailment is inevitable, with or without pulp-wood imports. For mechanical pulp the prospects are far less favorable, because it depends chiefly upon spruce, uses hemlock only at a comparative disadvantage, and finds jack pine still less satisfactory.

Possible timber production under intensive forest management will be considered for the three Lake States as a group. It may, however, be stated here that the possibilities of growing hemlock in the future are not very bright under any methods of management now known. The amount of spruce grown in Wisconsin will not be large enough because of the relatively small area of spruce lands in the State. It should be possible to grow very much larger quantities of jack and other pines, from which, if proper methods can be developed, the sulphite if not the mechanical-pulp industry can be perpetuated.

#### MINNESOTA.

Mechanical and sulphite pulp and newsprint paper are the chief products of the Minnesota mills. Minnesota imports no pulp wood from Canada but rather, as stated, ships a considerable amount into Wisconsin. Fully 99 per cent of the 1920 pulp-wood consumption of the State was spruce, and unfortunately the stand of this timber is relatively small and widely scattered. Because of the latter fact, probably not over half of the total estimated spruce stand of 5 million cords can be counted on for the immediate future, and even less of the 3 million cords of fir, which is defective. (Table 59.) The lumber and pulp-wood cut together, including shipments to Wisconsin, and without the cut for other purposes, losses from fire, insects, and disease are probably nearer 600,000 than 500,000 cords annually. Losses of both balsam and spruce are known to be large already from an attack of the spruce bud worm which has assumed epidemic proportions. The extent of replacement by current growth is unknown.

According to the best data available, therefore, the future of sulphite and mechanical-pulp making in Minnesota is very precarious if reliance is to be upon spruce alone. There is, however, a much larger stand of jack pine, estimated at 16 million cords, to which sulphite requirements, if not those for mechanical

pulp is being diverted to supplement failing spruce supplies. Unfortunately, however, entomologists believe that an epidemic of jack-pine sawfly, which has already done extensive damage in Canada, now threatens the jack pine of Minnesota and the Lake States. There is also a relatively large stand of aspen of good quality, estimated at 15 million cords, which might be made the basis of a soda-pulp industry of perhaps 100,000 cords a year. This species is now being cut for soda pulp only in very small quantities. There is also a stand of tamarack suitable for sulphate pulp, estimated at 15 million cords, but 60 per cent dead. Dead tamarack, however, remains suitable for pulp wood for a long period.

#### FUTURE TIMBER GROWTH IN THE LAKE STATES.

The total area of spruce-fir lands in the Lake States is about  $4\frac{1}{2}$  million acres, slightly less than half that in New England, but nearly twice that in New York. (Table 46.) Growth under intensive forest management will probably average slightly less than in either. It is estimated that, under intensive forest management upon the entire area, approximately 1,360,000 cords of spruce and fir could eventually be grown each year. (Table 56.) This, for all three states, combined, would leave a margin of about 400,000 cords of spruce and fir in excess of the total 1920 spruce-fir lumber cut and pulp-wood consumption, including imports from Canada. The latter amount would be available to replace hemlock, or for an enlarged pulp and paper production, or for other uses.

Possible growth in the pine type, under intensive forest management, has been estimated at more than  $12\frac{1}{2}$  million cords a year. The white and Norway pine of which the stand is composed in part would probably be so valuable for other purposes that they would be available only to a small extent for pulp and paper making. It is reasonable to assume, however, that possibly 1 to 2 million cords a year of jack pine, which is also produced in the pine type, would be available for pulp. In addition to a possible use for sulphite pulp, it is entirely suitable for sulphate pulp. Instead of waiting for the general development of forestry over the entire area of pine lands it would be entirely feasible for the pulp and paper industry to devote a part of these lands to jack-pine production, and thereby meet their own requirements. Tamarack also is suitable for sulphate pulp and may become a factor if the sawfly can be controlled.

Growth in the beech-birch-maple type can also be brought to a very large figure, in excess of 10 million cords a year. Possibly methods of timber growing may be developed under which hemlock can be kept an important species in this type as at present. It is rather to be expected, however, that the 530,000 cords (1920) of hemlock now used for pulp will, after the exhaustion of virgin supplies, have to be secured largely or altogether from other species. In any case the type includes species of value for soda-pulp manufacture, and a large volume compared with present use would be available, notwithstanding large present and probable future demand for these species for lumber and similar purposes.

On the whole, therefore, from the standpoint of timber production alone, there is a possibility, under intensive forest management, of a more varied and a very much larger permanent pulp and paper industry than at present, although there are very definite limitations on the size of the industry which can be supported on spruce and fir alone, and hemlock apparently offers little beyond two decades. Altogether, with a possible annual growth of nearly 31 million cords of pulp species, a pulp cut of any amount up to 5 million cords would not be unreasonable.

#### PACIFIC COAST STATES.

The preceding discussion of the three State groups where the American pulp and paper industry is now centered clearly indicates the serious objections to enlarging the spruce-fir-hemlock cut sufficiently to make up all or any part of the

present pulp-wood imports of 800,000 to 900,000 cords until the rate of timber growth can be increased through forest management. An enlargement to reduce pulp and paper imports or an expansion to cover in whole or in part the normal future growth in our requirements would be still more out of the question. Unless temporary relief can be secured through new pulping processes, a reduction of the cut is probable or certain in several of the States within a relatively few years under the most favorable conditions which can be anticipated.

To produce at home the pulp and paper now imported, and probably in part at least to absorb pulp-wood imports, it will therefore be absolutely necessary to turn to new regions. The regions which must receive first consideration are those which can furnish large quantities of spruce, fir, and hemlock, since upon these 78 per cent of our requirements depend. There will be great advantages in being able to go to regions with virgin timber supplies which can support an industry while forest production is being got under way. Two regions, Alaska and the three Pacific-Coast States—Washington, Oregon, and California—offer exceptional opportunities in this respect. Almost any new region may incidentally involve the solution of relatively minor technical difficulties as a phase of the development of large new industries.

The opportunity in the Pacific-Coast States for the development of a greatly enlarged sulphite and mechanical-pulp industry is based upon supplies of virgin spruce, fir,<sup>9</sup> and hemlock much larger than in any other forest region of the United States. Still larger stands of pine afford a similar opportunity to increase the production of sulphate pulp and the grades of paper, such as wrapping and boards, of which it forms a part. The three States contain a very large and well-developed lumber industry, which is still expanding rapidly, so that any enlargement of a pulp industry must, to some extent at least, compete with other use of timber. While the national forests of the coast States contain large amounts of timber, still more is in private ownership.

The Pacific Coast States contain of all species about half of the remaining saw timber of the United States. They contain about one-fourth of the stand of pulp species in cords. More than one-third of the total stand of these States, or nearly 900 million cords (Table 60), consists of pulp species, and a little more than 400 million cords of the pulp species are suitable for sulphite and mechanical pulp, while all of the remainder is suitable for sulphate.

It was estimated in 1920, in the report on Senate Resolution 311, that the total drain on the forests of this region exceeded replacement by growth by about three and one-half times. This is partly due to the large cut, supplemented by fire and disease, and partly also to relatively large stands of virgin timber, in which such growth as occurs is offset by the deterioration of the old trees. Utilization for lumber still leads by far all other forms, probably constituting 95 per cent of the total cut. Washington has, in fact, led the country in volume of lumber cut since and including 1905, with the exception of one year.

#### SPRUCE-FIR-HEMLOCK PULP WOOD FOR SULPHITE AND MECHANICAL PULP.

Half of the 400 million cords of sulphite-mechanical pulp timbers is western hemlock, and the remainder Sitka spruce and various true firs, obviously not including Douglas fir. The hemlock and spruce occur almost entirely in Washington and Oregon, the fir in all three States. Sitka spruce occupies a relatively small area on or near the coast. Hemlock, while sometimes in pure stands, ordinarily occurs in mixture with spruce or frequently with Douglas fir. On the high slopes of both the Cascades and the Sierras are pure stands of various firs, but ordinarily this group of species is found with other trees in practically all of the types of the region. The scattered manner in which some of the trees occur, the inaccessibility of a part of the stand, and the loss of some of the mate-

<sup>9</sup> Includes the true firs but not the species known as Douglas fir.

rial in logging operations will make a large but uncertain amount unavailable for pulp and paper manufacture.

Lumbering operations of the past have commonly discriminated against hemlock and the firs. Very often a large part of the hemlock found in Douglas fir stands has been left because it could not be manufactured profitably into lumber. This is less true to-day of hemlock, because general depletion of timber supplies has brought a growing appreciation of its intrinsic value. It still holds true, however, of much of the fir. The spruce occurs in quantity in a relatively limited territory, so that, all things considered, the cut of the mechanical-sulphite species for lumber has been small up to the present. In 1922 it reached, in fact, only about  $1\frac{1}{4}$  billion board feet out of a total lumber cut for the three States of about  $10\frac{1}{2}$  billion board feet.

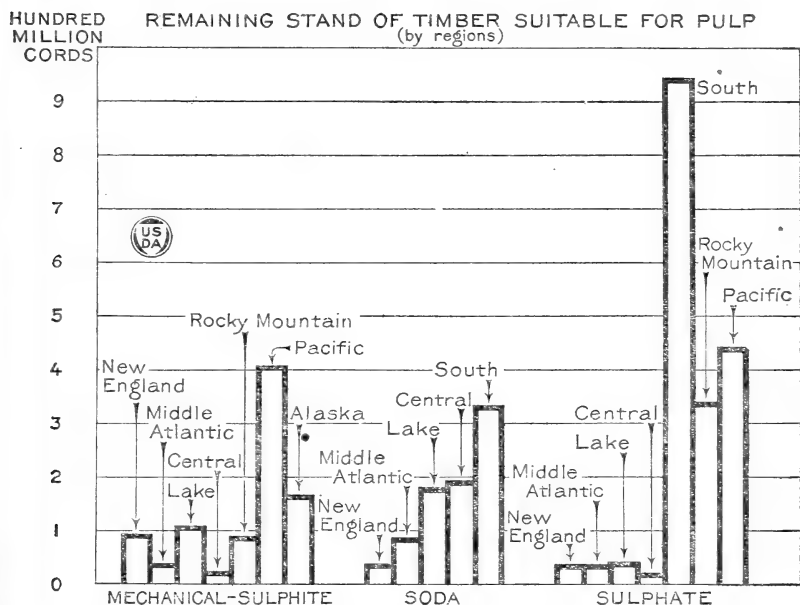

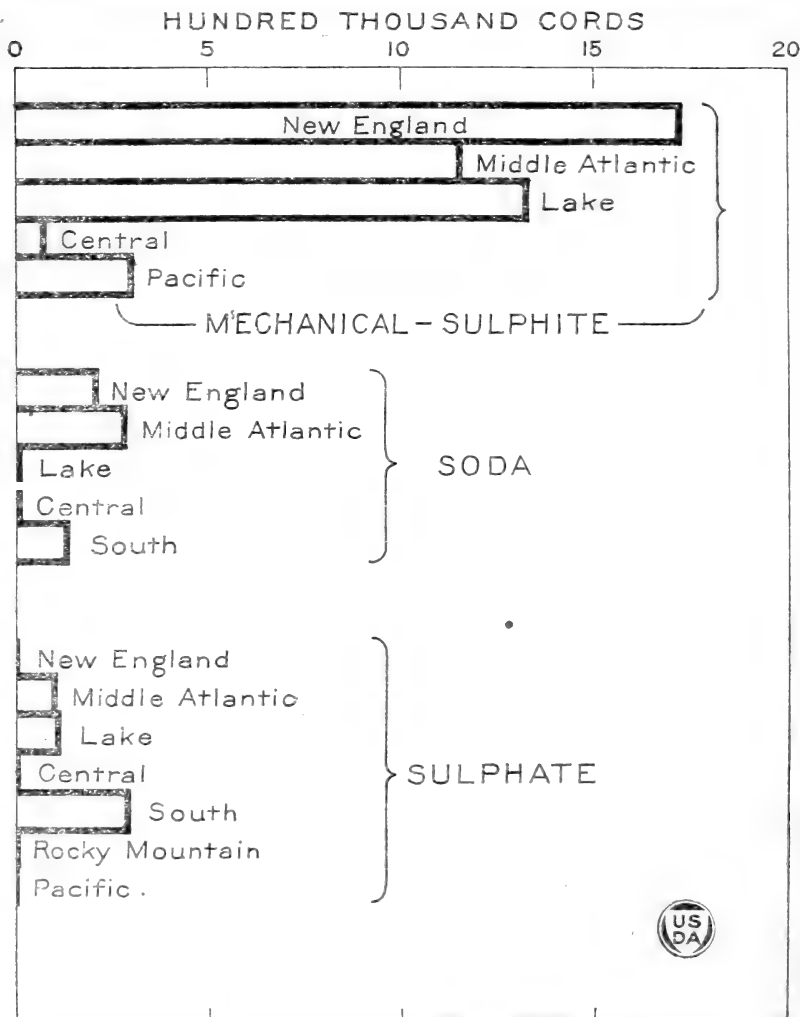

FIG. 27.—The immediate availability of the remaining pulp-timber supplies is greatly reduced by their distribution, the great bulk of the stand being in regions which now have few pulp mills. Pine constitutes a very large part of the remaining supply, but present demands are relatively small.

A comparison of the total stand of spruce, fir, and hemlock on the Pacific coast with that of regions now using similar species for pulp will give a somewhat better idea of the possibility of an enlarged pulp-wood cut than a mere statement of total stand. The total stand in the Coast States is more than six and one-half times that of related species in New England, but the cut for all purposes is smaller in the West by nearly 450,000 cords. The three Western States contain more than 10 times the spruce, fir, and hemlock stand of New York and Pennsylvania, but the cut of the latter States is more than half that of the Western States. The relationships outlined, of stand to present cut, are shown graphically in Figures 27 and 28. We are now taking approximately 3,345,000 cords of pulp wood alone from the spruce-fir-hemlock forests of New England, the Middle Atlantic, and the Lake States combined. The Pacific Coast States, with twice the total stand, could probably, with anything approaching the same standard of utilization as in the East, be expected to furnish an equal amount in the near future. This would mean an increase of more than 3 million cords

over the 274,000-cord pulp-wood cut of 1922. There is no apparent reason why the use of these species in the Pacific Coast States for pulp wood should not become the dominant use.

Washington, in which logging operations are most fully developed, contains by far the largest amount of spruce-fir-hemlock timber on the Pacific coast. A

### REGIONAL CONSUMPTION OF PULPWOOD BY PROCESSES, 1920

FIG. 28.—The pulp-wood cut is now centered in the Middle Atlantic, New England, and Lake States, where, as shown by Figure 27, the remaining stand of pulp timber is relatively small.

field study into the possibility of securing pulp wood from logging operations was made in 1920 in the part of the State west of the Cascades. It showed the possibility of securing at that time approximately 500,000 cords a year of low-grade hemlock, spruce, and fir logs, which have usually been difficult to sell and which could undoubtedly be used more advantageously for pulp. It was found that

it would easily be possible to secure from the area logged over annually, an additional 135,000 cords, by taking out material of saw-timber size but a little smaller than that which is now logged for lumber. Without, therefore, taking into account the possibility of utilizing a very large amount in small trees and broken material now left in the woods, and of using sawmill waste, the study disclosed the possibility of securing 635,000 cords of pulp wood from 1920 operations designed primarily for lumber.

There is no reason other than lack of pulp-wood markets why there should not be operations in Washington designed primarily to secure pulp wood, or why operations in stands containing a large percentage of pulp species should not be designed to secure saw timber from the material most suitable for that purpose and pulp wood from the remainder of the stand. There are great possibilities in the integration of the lumber and pulp industries, which, as will be shown later, would make entirely feasible large use of both logging and sawmill waste for pulp.

Furthermore, as the lumber cut of Washington increases during the next decade or so, which it promises to do, the amount of pulp wood available in connection with lumbering operations should increase. More and more as these operations proceed they will include stands of timber with higher percentages of the pulp woods and lower percentages of the Douglas fir, which is now chiefly sought. This might for some time offset largely or altogether a gradual falling off in the lumber cut in Washington, the beginning of which may not be more than a decade or so ahead.

The total stand of timber in Oregon is larger than in Washington, but the percentage of pulp species is lower; and except for the fir stands on the higher slopes of the Cascades the pulp species are more scattered in mixtures with other timbers. The amount of timber in Oregon now inaccessible is relatively higher than in Washington. It is reasonable to expect, therefore, that the pulp timber which will become available in the immediate future will be largely in connection with lumbering operations. The anticipated decrease in lumber cut in the South is certain to stimulate that of Oregon, and this should afford an increasing opportunity to utilize the pulp timber which occurs in mixture. In fact operations designed to secure both saw and pulp timber can be made more advantageous than for saw timber alone. Practically all of the pulp wood cut in Oregon now comes from lumbering operations.

Fir occurs in considerable quantities in the California pineries, and it should be possible to remove it economically for pulp wood in connection with lumbering operations. In California reliance can also be had upon the pure fir stands of the upper Sierra slopes. The sulphite and mechanical output that can be developed in California, however, is smaller than that in Washington or Oregon.

The question of available water power is also an important consideration in connection with an enlargement of the pulp and paper industry, and particularly in connection with the manufacture of mechanical pulp. Part 2 of Senate Document 316, "Electrical power development in the United States," places the estimate of the total potential water-power resources of the States of Washington, Oregon, and California at approximately 11½-million horsepower minimum, as compared with a little less than 28 million for the entire United States, and slightly more than 23-million horsepower maximum, as compared with the total of slightly less than 54 million for the entire United States. Water powers, potential if not developed, are accordingly large enough to encourage rather than retard any possible enlargement of the pulp and paper industry. Since the cheapest and most accessible powers have generally been developed and are in use by other industries, water power for an enlarged pulp and paper manufacture would be more expensive than in Alaska.

Within the time available it has been impossible to study the economic possibilities of competition by the west coast industry in eastern pulp and paper markets. Washington mills in 1920 paid on the average \$10.90 per cord for hemlock and spruce pulp wood, delivered at the mill, while New York mills paid \$25.01 per cord for spruce under the same conditions. This one item of cost of wood at the mill would go a long way toward offsetting the freight on paper from the west coast to Atlantic ports. An enlarged future demand would on the one hand tend to increase prices through competition for stumpage, and on the other to reduce the cost of delivering pulp wood at the mill through a larger, better established, and more effective organization for this purpose.

The future possibilities of a mechanical-sulphite pulp industry on the Pacific coast, present pulping processes considered, depend primarily upon the yields which can be secured of spruce, fir, and hemlock under intensive forest management. Unfortunately no data are available which show separately the potential growth of these species. They occur primarily in mixture with nonpulp species, and the growth and yield figures available cover types rather than individual trees. The greater part of the existing stand occurs in what is classified as the Douglas fir-spruce-hemlock type, which on the Pacific coast includes an area in excess of 25 million acres. (Table 46.) While present growth of this type falls somewhat short of  $5\frac{1}{2}$  million cords a year it is estimated that under intensive forest management production could ultimately be increased to more than 24 million cords. From this total it would appear entirely feasible to maintain permanently a pulp and paper industry consuming from 3 to  $3\frac{1}{2}$  million cords a year. This is the approximate volume already indicated as that to which the spruce-fir-hemlock cut of the near future might be increased.

In this survey it must be kept in mind that possible growth in the Douglas fir-spruce-hemlock type is much faster than in the corresponding types of the Northeast and the Lakes States. While the average possible growth under intensive forestry for the spruce-fir type in the Northeast as a whole is estimated at 45 cubic feet per acre per year, and in the Lake States at 35 cubic feet, that for the coast Douglas fir-spruce-hemlock type has been placed at 112 feet. The possibilities in the Northeast, on small tracts under exceptionally favorable conditions, of 80 cubic feet per acre per year may be increased on the Pacific coast to 170 cubic feet. Assuming the production of pulp species alone, it would require an area of only approximately 8 million acres on the west coast to produce our total spruce-fir-hemlock pulp requirements of about 7,170,000 cords. This area is only a little over half of the forest area of Maine. Production of the  $3\frac{1}{2}$  million cords indicated for the Pacific Coast States would require only 4 million acres, with correspondingly larger areas if nonpulp species or if less intensive methods of management were involved. It would be entirely feasible, if the pulp and paper industry desired, to produce its future requirements on a relatively small aggregate area.

Still another future advantage lies with the Pacific coast forests. Growth is so rapid that pulp wood may be produced on very short rotations. While rotations of 50 years as a minimum will probably be necessary in the eastern spruce forests, it should be entirely feasible with similar standards of utilization to grow spruce, fir, and hemlock in the Pacific Coast States on rotations of 30 years.

#### PINE PULP WOOD FOR SULPHATE PULP.

The preceding discussion has dealt entirely with possibilities of sulphite and mechanical pulp production. The three Pacific Coast States, however, contain more than 490 million cords of pine and other species suitable for sulphate pulp.<sup>10</sup>

<sup>10</sup> The possibility of using Douglas fir for sulphate pulp is not taken into account although a small volume is now being used. A very small amount of Douglas fir is also being used with cottonwood in the manufacture of book paper. The existing stand of Douglas fir is very large, probably two or three times that of pine and other species suitable for sulphate pulp in the Pacific Coast States. The possibilities for growing Douglas fir are also very large.

(Table 60.) Nearly all of this timber is pine, and mostly western yellow pine. The total drain upon the sulphate-pulp species probably reaches about  $3\frac{1}{2}$  million cords annually, and it exceeds the current growth six or seven times, for essentially the same reasons as those given in the case of the sulphite-mechanical pulp species.

Under intensive forestry, however, it should be possible to grow annually in excess of  $12\frac{1}{2}$  million cords. Much of this will be needed and cut for saw timber, but a large volume would undoubtedly be available for sulphate-pulp manufacture from thinnings and defective logs and trees. Western yellow pine particularly makes a very satisfactory wrapping paper. Under forest management it should not be difficult in the future, if not immediately, to secure from the pine stands of the Coast States any desirable part, or all, of the 773,000 cords of sulphate pulp wood now imported in one form or another from Canada and Europe, or in addition, to take care of the annual increase in requirements of 110,000 cords for some years to come.

#### ALASKA.

Alaska, as already indicated, is one of the two outstanding regions with large virgin supplies of softwoods adapted to sulphite and mechanical pulp. As compared with the Pacific Coast States, Alaska has the advantage of practically pure stands of these species of pulp timber, lower stumpage prices, and cheaper power. It has the disadvantage of being considerably farther from the large paper markets, and of pioneer conditions which would tend to hamper the development of an industry. Ordinarily the pulp and paper industry has followed lumbering, and has either had to displace the sawmill through competition or to take the material which the sawmill left. In Alaska, however, cutting operations for lumber and other purposes are small, so that in this respect there would be a greater opportunity for the development of a dominant pulp and paper industry than in the Pacific Coast States.

To insure the development of the pulp and paper industry on the basis of continuous and permanent supplies ample to meet requirements, the area of the two national forests in Alaska, to which this discussion is confined, has been divided into allotments or compartments. Each of these compartments is of such a size and character that with available timber resources and water power a pulp plant will be permanently supported and such additional timber furnished as may be needed by sawmills for local needs. Under this plan there can be no overdevelopment of manufacturing plants in relation to raw material.

The forest itself forms the northernmost extension of the heavy coast forest of Washington and Oregon. In the western part of the area under consideration it merges with the interior forests of white and black spruce which extend entirely across the continent from the Atlantic. Sixty-five per cent of the 80 billion feet, board measure, consists of western hemlock, already proved by actual use to be a satisfactory sulphite-pulp-wood species; and an additional 20 per cent or more consists of Sitka spruce, comparable in its properties for both mechanical and sulphite pulp with the various spruces of the eastern United States and Canada. While these species are suitable for construction and box material, general lumber requirements, piling, and similar purposes, and are being so used in increasing quantities, the general belief of those most familiar with the Alaskan forests is that their great future use will be for pulp and paper. This is especially true of the Tongass National Forest, in southeastern Alaska, which contains more than seven-eighths of the total stand.

With due allowance for the probable cut into other products and with consideration of the timber below saw-timber size, these forests unquestionably

contain 100 million cords available for pulp wood, and probably even a larger amount. The estimates are based upon intensive cruises covering nearly 600,000 acres, upon more extensive cruises covering nearly 800,000 acres in addition, and on a general knowledge of the remainder of the area. The surveys have disclosed stands running as high as 200 cords to the acre. An average stand of nearly 40 cords to the acre was found on one large pulp and paper tract.

The pulp and paper industry can no longer afford to locate in new regions on the basis of existing stands of timber alone. It must inquire also into the productive capacity of the soil and the timber species which can be grown. The heavy rainfall of southeastern Alaska insures rapid growth, not equal, to be sure, to that of western Washington and Oregon, but probably far in excess of anything that can be hoped for in the Middle Atlantic, New England, and Lake States. Using only the estimated growing rate of the spruce-fir forests of New England, the Alaskan forests will easily produce 2 million cords of pulp timber each year. From the standpoint of permanent supplies, it will be safe, in the judgment of the best informed foresters, to develop in the immediate future a pulp and paper industry up to these requirements.

The production of the Alaskan forests is more than twice enough to make up the 800,000 to 900,000 cords of spruce-pulp-wood imports from Canada. It would take up for eight and one-half years the normal annual increase of 237,000 cords of spruce, fir, and hemlock for sulphite and mechanical pulp. It is more than half of our total dependence for pulp wood, pulp, and paper from all countries, equivalent to 3,916,000 cords, derived from these species. The total cut of spruce and fir for Canadian mills was 2,660,611 cords in 1922. Alaska has frequently been described as a second Norway in its possibilities for pulp and paper making. Yet the Norwegian industry consumes only about 1 million cords a year, and that only by overcutting. Swedish consumption has reached about 3 million cords.

The pulp and paper industry can not, however, depend upon timber supplies alone. Abundant and cheap water power is equally essential, especially in the manufacture of mechanical pulp. It will require not to exceed 500,000 horsepower of continuously available power to convert 2 million cords of pulp wood a year. Four hundred thousand horsepower is already known to be available in southeastern Alaska, 325,000 horsepower of this in sites or groups of 5,000 horsepower or more that can be developed economically for pulp manufacture. These statements of water-power resources are based upon data collected in a systematic survey which the Forest Service has had under way for a number of years, in cooperation with the water-resources branch of the United States Geological Survey and with the Federal Water Power Commission. Intensive surveys have still to cover half or more of southeastern Alaska. A considerable but unknown amount of power can be developed from the flood waters of large rivers for about six months of the year. A few airplane flights over southeastern Alaska have indicated a large number of lakes which had not previously been mapped but some of which will undoubtedly be of value for storage purposes. Economic development and ability to pay higher prices for power will increase the number of sites that can be developed.

To conditions favorable to the development of a pulp and paper industry must be added suitable mill locations and deep-sea transportation. Mills can be located within easy and cheap towing distances from adequate timber supplies. Sheltered channels afford yearlong deep-sea transportation, and the advantages which such transportation affords for incoming supplies and for outgoing products.

Both timber and power can be secured from the Forest Service and Federal Power Commission, respectively, under terms which President Harding in his Seattle speech on Alaska described as follows:

"I venture, with some knowledge of conditions in various paper-making countries, to state that no better contract, indeed none so good, can be secured in any of them."

The development of the pulp and paper industry has unquestionably been retarded by the pioneer conditions which obtain in Alaska. The relatively few settlements are rather widely scattered. This means, among other things, the lack of local skilled labor, particularly for a new industry, which would also have to contend with a lack of local supplies and with the absence of machine-shop facilities. These conditions would necessitate the carrying of larger stocks at the plant and relatively long delays in securing new materials and parts by boat from the Pacific coast or by the Canadian railroads.

Capital moves slowly into new regions, and this is especially true in industries, such as pulp and paper manufacture, requiring large initial investments. While the great development of pulp and paper manufacture in the United States has come during the last three decades, the failure to meet American demands has increased most rapidly during the last decade, a period much of which has been so unsettled as to make pioneering efforts especially hazardous. American capital has gone to the eastern Canadian forests, which are nearer to American centers of consumption and in which conditions are more comparable with those in the Northeastern and Lake States. Alaska has seemed very remote, and until recent years there has been an absence of the detailed, authoritative data necessary to secure real interest on the part of capital. Ocean freights, with a relatively small volume of traffic, have been high. Alaskan timbers are suitable for newsprint production, and until the war newsprint prices particularly were relatively low.

Neither time nor the funds available have permitted an attempt to secure exact data on the possibility of successful competition of Alaska in eastern pulp and paper markets with Canada, or even with American mills. A few significant facts, however, will be given. Average prices paid by American mills for imported spruce were \$27.98 per cord in 1921 and \$21.87 per cord in 1922. Since these were average prices, many mills must have paid more. In one large pulp unit on the Tongass National Forest, the timber on which was recently sold, it was estimated that, exclusive of a purely nominal figure for stumpage, the cost of pulp wood at the mill from the more accessible timber on the area would not exceed \$5.50 per cord, and that for the entire sale area the cost would be approximately \$8 per cord. These estimates are based on 1923 wage scales and mill costs. They leave a large margin for the payment of freight from Alaska to eastern markets, as compared with spruce-pulp-wood prices of 1921, or even 1922. This is particularly true if the concern which undertakes a pulp and paper development finances its own system of ocean transportation.

#### SOUTHERN STATES.

Second in importance to our dependence for sulphite and mechanical pulp woods is that for sulphate pulp wood. As shown by Figure 27, the southern-pine States from Virginia to Texas contain far and away the largest supply of suitable timber and have the additional advantage of easy access to the principal markets of the country. Two-thirds of the timber stand of these States, or nearly 1,300 million cords, is of species used to a greater or less extent for pulp (Table 61), and the greater part of this is pine.

The South Atlantic and Gulf States, considered separately in the report on Senate Resolution 311, are here combined because of similarity of conditions and

of pulp timbers. They contain nearly 178 million acres of forest land. (Table 46.) The States of this region have, since the passing of white-pine supremacy, led the country in lumber production, but the cut of pulp-wood timber has always been insignificant. In 1920 it reached only about 440,000 cords, not including slabs and waste. The virgin stands which have largely supplied the lumber cut of the past are fast disappearing.

#### SPRUCE AND HARDWOOD PULP WOOD.

Less than 10 million cords of the total stand are of the spruce-fir-hemlock group, the stands of which are very heavy and occupy a relatively limited area on the higher slopes of the southern Appalachian Ranges. These stands, while of great present value, have much less significance in an enlargement of the existing industry or the development of a permanent pulp and paper industry than similar amounts of the same species in either New England, New York, or the Lake States. The possibility of reproducing these forests is much less certain, so that no safe prediction can be made as to their future as sources of pulp-wood supplies.

Various soda-pulp species—cottonwood, birch, beech, maple, yellow poplar, basswood, and red, black, and tupelo gums—are scattered over an enormous territory and aggregate 335 million cords. The remaining virgin stands are chiefly in the lower Mississippi bottom lands and along the Gulf coast. A large part of the other hardwood stands have been more or less heavily and repeatedly cut over in the past. Considerable areas are now chiefly valuable for fuel or pulp wood. While cutting far exceeds growth, there are undoubtedly many areas from which a large volume of pulp material could be taken as thinnings and improvement cuttings, and in fact its removal might be made to constitute one step toward better forest management. It should easily be possible to take care of our present shortage of 196,000 cords of soda-pulp-wood timber from this territory if proper methods of forest management begin with the cutting, and to enlarge this at the rate of 23,000 cords a year to absorb our increasing needs for years to come. Relatively small areas could, if worked for pulp timbers alone, be made to produce the entire volume required.

#### PINE PULP WOOD FOR SULPHATE PULP.

Three-fourths of the pulp stand consists of various species of southern yellow pine, amounting to about 940 million cords. (Table 61.) Under present pulping processes it is being utilized almost exclusively for sulphate pulp and wrapping paper and boards. A bare beginning has been made in its use as bleached sulphate pulp for book paper in substitution for sulphite pulp. The commercial feasibility of this practice has been demonstrated, and wider use is a distinct possibility. There is also the possibility of substituting pine, in part at least, for the spruce and hemlock used in sulphite and sulphate pulp for wrapping paper and boards. Potentially, as will be shown, there is the further possibility of using pine in larger quantities in a modified sulphite process. With present practices as the standard, however, the chief demand for this enormous southern pine resource will be to relieve our dependence for sulphate pulp.

The cut of southern pine now exceeds its growth by about three times. Such second growth as we have is almost entirely voluntary. Most of the stands, in fact, have persisted in spite of destructive lumbering and equally destructive naval-stores operations, and annually or periodically recurring fires. With a certain amount of care, the leaving of a few trees in cutting, fire protection during the critical stage of tree development, and similar measures, the growth of the

southern pines could be enormously increased. With a reasonably distributed industry and with the immediate adoption of forestry measures there should be no difficulty in taking care immediately, in the South alone, of our present total dependence upon foreign countries for an equivalent of 773,000 cords of sulphate pulp wood and of the annual increase in our needs of 110,000 cords a year. The demand for small material for pulp wood would undoubtedly stimulate rather than retard the interest in timber growing in the South through increasing the value of the product. Much of the material needed for an enlarged southern paper industry dependent on pine could be secured from desirable thinnings and from small or defective logs. Even without forest management the pulp and paper industry could probably expand in the South through ability to take a good deal of timber away from the lumber industry in a competitive market; but this could not be particularly desirable from the standpoint of the public.

The southern pines occur in both the southern-pine and the oak-pine type. Possible growth of the pine alone under intensive forestry is estimated at more than 40 million cords a year. Much of this will be needed for saw timber, fuel, and other purposes, but the total dwarfs present sulphate-pulp requirements of 1,220,000 cords and the current rate of increased demand so greatly that there should be no difficulty in meeting enormously enlarged future needs, provided the adoption of intensive forestry methods precedes or at least accompanies the development of the industry. If future developments make possible the use of pine for other pulps, a very large volume of pulp wood will be available. Some of the possibilities of such developments are discussed later. The pulp and paper industry has also the opportunity to devote relatively small areas exclusively to pulp-wood production. The total sulphate requirements could be grown on 2 million acres, for example.

Here, as in the West, is the opportunity for producing material of pulp-wood size in very short rotations. Fifteen to twenty years in the South will produce large yields of thinnings, which can be repeated periodically until it is desirable to remove the remaining stand for either lumber or pulp wood, or for both.

Other conditions in the South are believed to be favorable for an immediate and permanent future enlargement of pulp and paper making. The southern mountain streams furnish ample power. Forest lands occur in both large and small holdings. A pulp and paper concern has before it the alternative of acquiring its own lands or of placing its dependence upon the timber grown upon farm wood lots, or other and larger holdings. Operators desiring to locate in the South and to acquire their own timberlands are not restricted to denuded forest lands. It is easily possible to secure at relatively low prices partly grown stands for future needs, as well as timber already large enough for pulp.

In much of the South there is the possibility, with long-leaf and slash pines, of combining naval stores with pulp production or of combining both with lumber production, and finally of extracting the resinous products from the pulp wood itself. The South has a distinct advantage over the western pine stands in pulp and paper manufacture on account of the handicap to the Western States of distance from the great eastern and middle western markets.

#### ROCKY MOUNTAIN STATES.

The Rocky Mountain States afford an opportunity for enlarged sulphite and mechanical pulp operations in the near future, but to a much smaller degree than the Pacific Coast States or Alaska. They afford a similar opportunity for sulphate pulp, but here also in much smaller degree than in the Coast States or the South. The opportunity in both cases is based, as in Alaska and the Pacific Coast States, on remaining supplies of virgin timber.

The Rocky Mountain States embrace a large territory of varied forest conditions. The northern Idaho and western Montana forests are similar in many respects to those of the Pacific coast in Washington and Oregon. Relatively heavy stands of western yellow pine in the north grow gradually lighter to the south. Large areas are occupied by lodgepole-pine forests, resembling the jack pine of the Lake States. The forests of various mountain ranges, except in some cases in the north, are widely separated by open, treeless country.

The Rocky Mountain States now support fewer pulp and paper mills than any other forested region of the United States. This is partly a matter of density of population and local demand for paper, partly the economic impracticability up to the present of shipping pulp or paper long distances by rail to the markets of the Middle West and East. The handicap of the rail haul as contrasted with a possible water haul from the Pacific Coast States and Alaska may gradually disappear with increasing population in the Rocky Mountain and Middle Western States, the growing demand for pulp and paper, and the inability of eastern and western forests to meet requirements.

#### SPRUCE-FIR-HEMLOCK PULP WOOD.

More than four-fifths of all the timber of the Rocky Mountains is of the pulp species, estimated at 440 million cords. (Table 62.) The stand of 88 million cords of spruce, fir, and hemlock is larger than that of New England, much larger than that of the Middle Atlantic States, and nearly as large as that of the Lake States. Except in central and northern Idaho and northwestern Montana, however, the sulphite-mechanical pulp species are much more scattered and hence correspondingly less available. A part of the Idaho and Montana timber is inaccessible under present conditions.

Northern Idaho supports a well-developed lumber industry, the tendency of which has been, as in the Pacific Northwest, to pass by the spruce-fir-hemlock group of pulp species. Practically the only cut of the latter is for lumber, and for that the cut is small. A large amount of timber apparently suitable for pulp is being left on cut-over areas. A large portion of the central Idaho material is still inaccessible. There is an opportunity in the Engelmann spruce, fir, and hemlock stands of northwestern Montana for an enlargement in the immediate future of the sulphite and mechanical pulp output. Here the percentage of the spruce-fir-hemlock group is larger than in northern Idaho, and the lumber industry is much less developed, so that there would be fewer handicaps in securing material for pulp and paper mills. Water power is ample.

A great opportunity is afforded to increase the pulp-wood cut by a proper coordination of the lumber and the pulp and paper industries in logging, and the use by each of the material most suitable for its products. Such an arrangement should aid materially in reducing the amount of wood now wasted in logging operations because of lack of market, and could even include the use of sawmill waste for pulp manufacture. Pulp requirements need not, however, be secondary or incidental to lumber. They can, in fact, constitute the dominant use for spruce, fir, and hemlock.

Unfortunately, growth data for the species of the spruce-fir-hemlock group are not available, since they are ordinarily mixed in types containing nonpulp species. A part of the growth under intensive forest management in the Douglas fir-spruce and the white-pine types, totaling together nearly  $4\frac{1}{2}$  million cords, as well as that in the yellow-pine type reaching nearly 6 million cords, could be counted on. Possibly 1 million cords a year would not be unreasonable for pulp potentialities of the near future, and permanently thereafter.

## PINE AND LARCH PULP WOOD.

The sulphate-pulp pines and larch in the Rocky Mountain region together total about 342 million cords, a much larger present volume than that of the spruce group. White pine, the most heavily cut species now, will be in even greater demand for lumber in the future, so that only relatively small amounts, if any, will probably be available for pulp wood. Yellow pine, with a present stand of more than 135 million cords, is being a little less heavily cut now than white pine, but is certain to increase in demand for both local and general lumber markets. There is the distinct possibility, however, in regions of extensive stands that thinnings and low-grade logs could be used economically for pulp in connection with lumbering. The total amount available would probably be relatively small. The stand of lodgepole, a species entirely suitable for sulphate and possibly also, because of its similarity to jack pine, for sulphite pulp, is only slightly less than that of yellow pine—about 130 million cords. Lodgepole is now less in demand in the Rocky Mountains than either western yellow or western white pine. From the standpoint of supplies alone there are undoubtedly opportunities in Montana, Wyoming, Utah, and Colorado for its immediate use for pulp. Its growth under intensive forestry, estimated at  $4\frac{1}{2}$  million cords a year, should afford a permanent future supply. There is no apparent reason why the paper industry should not become one of the most important if not the major consumer of lodgepole pine. To the pines must be added larch, with a stand of 34 million cords.

The greatest possibility for sulphate pulp from the various species discussed is probably from lodgepole, with western yellow pine and larch second, and white pine a minor possibility; altogether they might supply from 1 to 2 million cords a year continuously.

## CENTRAL STATES.

The forests of the Central States, except for relatively small stands of spruce and fir in West Virginia and Tennessee, the scattered hemlock in the same territory, and the northern extension of the southern-pine stands in Tennessee and Missouri, are made up of a wide variety of hardwood-pulp species. One-third, or about 240 million cords, of the total stand in the region consists of pulp species, and four-fifths of the pulp stand is composed of about 10 hardwood species suitable for soda pulp. (Table 63.) Half of the total hardwood stand consists of birch, beech, and maple. The opportunity is for an enlargement of the pulp-wood cut of hardwood for soda pulp.

The Central States now support a large number of paper mills, which manufacture chiefly book and boards, but they have few pulp mills. As in all eastern and most western forest regions, the forest is being heavily overcut, at about four times the rate of replacement by growth, and a large area now supports only scrub hardwood trees with far too little promise of high-grade products, such as lumber. Properly conducted operations in such forests could be made of material benefit by the removal of poorer and more defective trees, thinnings, etc. Out of this could come an immediate increase in the supply of pulp wood for soda pulp, and as the forests are gradually brought under management any such enlargement of the industry could be supported on a permanent basis. With properly directed cutting, such an enlargement of pulp and paper manufacture could be made to stimulate rather than retard the development of forest management.

Paper manufacture would be handicapped as now by having to ship in sulphite pulp from other regions. The amount which could be secured from the spruce-fir-hemlock stands of the western Appalachian Ranges would be small, and possibly unreliable for a permanent industry.

Potential growth under intensive forestry of the four or five types containing soda-pulp timbers is very large, reaching nearly  $29\frac{1}{2}$  million cords a year. Out of this total could unquestionably be secured soda pulp wood enough to meet all of our present deficit of 196,000 cords, and in addition enough to meet for an indefinite period to come the annual increase in our needs which now amount to 23,000 cords. Relatively small areas devoted exclusively to the growing of soda-pulp species would produce the entire amount of the present and greatly enlarged future requirements.

### NATIONAL TIMBER GROWTH UNDER FOREST MANAGEMENT.

In some of the more critical types and regions, as for example the spruce-fir type in the Middle Atlantic States, the current pulp-wood demand alone would absorb all or more than the total estimated growth under intensive forest management. Intensive forestry on the entire area of the type would, therefore, be necessary to support an industry of the present size under present pulping processes. In other types and regions, however, the pulp and paper industry could meet its own requirements from relatively small areas of forest land intensively managed or from larger areas with a cruder system of forestry. The use of southern pines for sulphate pulp is a case in point. In either case pulp and paper concerns have the opportunity to secure and reforest land areas sufficient in size to meet their own supplies.

Regardless of whether either of these two or an intermediate condition obtains, however, the question of pulp-wood production and that of wood production for all other purposes upon the entire area of forest land, are so closely related that they can not be separated. The consideration of possible timber growth, therefore, affords a necessary background both from the standpoint of the public interest and that of the pulp and paper industry, for the solution of the whole pulp and paper problem.

### POSSIBLE GROWTH UNDER CRUDE FOREST MANAGEMENT.

Forest lands in every timber region of the United States can be kept productive by simple, practical, and relatively inexpensive measures. On some lands thoroughgoing fire protection alone will assure a new crop, not necessarily of the best species in the least time, and almost certainly with reduced yields, but still timber crops. In other forest types such additional measures as the reservation of seed trees or of the smaller trees at the time of cutting will be necessary. Such measures as these constitute a preliminary step toward intensive forest management.

Under such simple measures, however, it is estimated that the present annual growth in the entire United States of 5 billion cubic feet could be increased by 1950 to 10 billion. Ten billion feet, however, falls far short of the 25 billion feet now taken from the forests or destroyed, and at the present rate of use, timber scarcity is making itself felt in other products than pulp, including such important products as lumber and ties.

Simple forestry measures, however, if continued for a long enough period, could be made still more productive. The effect of cumulative fire protection would be pronounced and the area containing growing stands of timber would be steadily increased, so that ultimately it is estimated under these methods growth on our 470 million acres of forest land might be increased to 14 billion cubic feet. Fourteen billion feet is better than ten, but the possibility of this annual growth is far in the future and is still only a little more than half of what we now destroy or use from the forest each year. A limitation to any such production would inevitably mean a most drastic reduction in timber use in the

United States, affecting lumber and practically every other forest product. Pulp wood, because of its competitive advantages, might be better off than most of the others.

#### POSSIBLE GROWTH UNDER INTENSIVE FOREST MANAGEMENT.

Intensive forest management, which would force our forest lands to their greatest effort, will require effective protection against fire; and methods of cutting the mature timber that insure prompt and complete reforestation. It will require the selection and concentration of growth on the best species in each region. It will require cultural operations such as thinnings, which alone can keep the stand at optimum growth and which in Europe yield, and in this country may be expected to yield, a revenue from forest land before the main crop reaches maturity. It will require a cut so regulated that no more than the equivalent of the current growth in the whole forest will be taken annually or periodically. It will require a grasp of technical methods of timber growing comparable with what has slowly been developed for producing timber crops in Europe, and for producing agricultural crops in the United States. To make the practice of intensive forestry universal, or even the rule, throughout the United States can at best be only a gradual process. Forest land can not be brought to its full growing power in a short time.

Based upon the best data that we now have on the growth of American trees and forest types, checked by European experience, it is estimated that our 470 million acres of forest land could ultimately be made to produce in the neighborhood of 27 billion cubic feet annually. (Table 47.) Such a yield leaves a fairly comfortable margin over the present annual cut of  $22\frac{1}{2}$  billion cubic feet, but a rather narrow margin when the increased present drain, estimated at  $2\frac{1}{2}$  billion cubic feet, from fires, insects, and disease is added. Intensive forest management, however, must strive to reduce this loss. The more successful such efforts are, the greater will be the margin between present requirements and possible ultimate timber growth, with corresponding leeway for increased utilization to supply our growing demands for pulp wood, lumber, and other products.

The margin between the present drain on our forests and the possible growth on our entire area of forest land under intensive forestry exceeds 22 million cords, and more than half of this total, or something over 12 million cords, is of pulp species. We now lose about 20 million cords of timber each year through fire, insect infestations, fungous diseases, and windfall, and more than half of this is pulp timber. To these possible amounts of wood that may become available in the continental United States, must be added 2 million cords a year to cover estimated growth in southern and southeastern Alaska. There is thus a possible total of 14 million cords, plus the 5 or 6 million cords additional which ought to be saved from fire, insects, and disease, to be drawn upon in providing for an increase of our pulp-wood cut from the present  $4\frac{1}{2}$  million cords to the objective of 15 million cords previously set. To what extent this timber will, if grown, be actually available for use by the pulp and paper industry will depend upon the amount and severity of competition by other industries for the same timber.

The possibility of using small timber from thinnings, thereby increasing timber growth, and of using the smaller and more defective logs in connection with operations requiring high-grade timber, should tend to make the solution of the problem much easier. Our greatest future difficulties will unquestionably be in supplying the high-grade material for such products as lumber, which requires a long growing period. It is fortunate that our resources are not limited to the possibilities of growing pulp wood on the basis of present manufacturing practices, which alone have been included in the estimates of possible pulp-wood cut in the regional discussions.

## ESSENTIAL SUPPLEMENTARY MEASURES FOR MEETING REQUIREMENTS.

Increased use of logging and sawmill waste through closer correlation of the lumber and pulp industries, increased use of waste paper, and reduction of waste in pulp and paper manufacture afford possible ways to reduce the drain on the forest for our paper requirements. At the same time, a wider use of species would tend to distribute the problem of pulp-wood supply more widely and to make its solution easier.

### UTILIZATION OF LOGGING AND SAWMILL WASTE AND INTEGRATION OF TIMBER-USING INDUSTRIES.

Census reports indicate that the use of logging and sawmill waste in pulp making is decreasing in the United States. The quantity thus utilized in 1922, about 88,000 cords, was only about one-third of that in 1909, the first year for which figures are available. (Table 5.) The decrease has accompanied rapidly increasing pulp-wood prices. There are probably a number of reasons for this unexpected falling off. Lumber manufacture in any one sawmill set or location has hitherto been largely temporary, and the pulp and paper industry has ordinarily come in near the close of the major lumbering operations. In fact, in New England and New York it has been hastening the exit of lumber manufacture. Probably, therefore, there has been greater and greater difficulty in securing sawmill waste. If European experience is a guide, another factor of importance is the organization in the United States of lumber and pulp and paper manufacture as separate industries having no relation to each other. The general result probably is that pulp manufacturers find it so troublesome and expensive to secure logging and sawmill waste from lumber companies that its use has gradually been discontinued.

It is shown in the article entitled "Timber: Mine or crop?" published in the 1922 Yearbook of the Department of Agriculture, that the waste in primary lumber manufacture in the United States amounts to approximately 5.13 billion cubic feet a year. Deducting the possible lumber saving through improved methods of manufacture and utilization, there would still remain unutilized an enormous volume of material, equivalent to more than 40 million cords a year. More than half of the present stand of timber in the United States is of species suitable for pulp, and the lumber cut of the pulp species is roughly in proportion. It is entirely out of the question to expect the utilization of any large proportion of this waste for years to come. But with the pressure of high pulp-wood prices, the insistent demands of a growing population for paper, the development of a more stable lumber industry based on a succession of forest crops, and the coordination, as in Sweden, of lumber and pulp utilization, it should in time be possible to utilize several million cords of waste a year.

In Sweden, for example, most of the large sawmills have box factories, planing mills, charcoal plants, and finally sulphite and sulphate pulp mills which operate partly on logging and sawmill waste and partly on logs which can not be sawed profitably into lumber. These groups of mills operate under single control, so that it is possible to divert logs from one product to another as conditions warrant. It is reported, in fact, that the entire Swedish pulp and paper industry, one of the most important in the world, operates incidentally to a forest management designed for saw-timber growing. No wood is cut primarily for the Swedish pulp mills. Thinnings are made to meet the requirements of the forests, and this, with poorer logs and sawmill waste, constitutes the entire supply of raw material for pulp.

This is the ideal arrangement, to which the correlation of the lumber and pulp industries in the United States should come in many regions. That it is feasible

even now is shown by large enterprises in the South and in the Lake States which combine lumber manufacture on a large scale with pulp and paper manufacture on an almost equally large scale. There is at least one concern in New England which follows the same plan to great advantage. Several of the pulp mills on the Pacific coast and many of the mills in the Lake States are dependent in part or altogether upon poorer logs cut during the lumber operations.

But we still have a very long way to go before we can approach the Swedish ideal. With a forest area of approximately 55 million acres, all of which lies above the northern limit of the United States proper, and with a timber growth still short of the full capacity of its soil, Sweden is able to produce annually about 3 million cords of pulp wood. On the same scale the United States, with its 470 million acres of forest land, and with a potential average production more than that of Sweden, should be able, as illustrated by Figure 29, to produce at least 26 million cords of pulp wood as an incident to lumber production, even though a much smaller proportion of our species are now regarded as suitable for pulp.

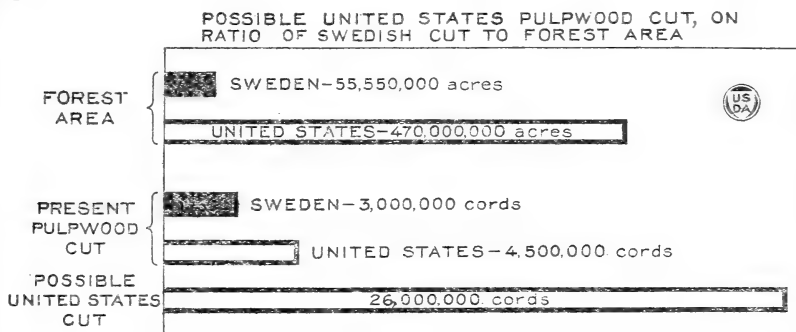

FIG. 29.—If Sweden can cut 3 million cords of pulp wood from 55 million acres of forest land annually, the United States, with forest management and balanced utilization, should be able to cut 26 million cords on the same ratio. The possibilities in the United States are even greater. Practically all of the Swedish species are suitable for pulp, while in the United States pulp species form only about 55 per cent of the present stand of timber. But average growth in Sweden is 24 cubic feet per acre, while that estimated for the United States is 58 cubic feet, more than twice as much.

#### INCREASED USE OF WASTE PAPER.

Reuse of waste paper, now about 85 per cent wood, reduces correspondingly the annual demand on the forests. American mills consumed a little less than 140,000 tons of waste paper in 1889, or about 12 per cent of the total volume of paper consumed that year. In the next 30 years the use of waste paper grew to nearly 1,855,000 tons, or about 29 per cent of the total volume of paper consumed.

One great obstacle to more extensive use has been the lack of a satisfactory de-inking process, but this obstacle has now been surmounted from a technical standpoint if not from that of actual commercial operation. The cost of collection and storage now limits reuse to large centers of population, but the possibilities in this direction are still far from exhausted. More general municipal collection and utilization of waste materials will tend to increase the amount of waste paper available, while higher prices will tend to make more and more feasible the use of this paper.

#### REDUCTION OF WASTES IN PULP AND PAPER MANUFACTURE.

Investigations have shown that decay causes a large waste in both pulp wood and pulp storage. Pulp wood stored under unfavorable conditions for two or three years has been found in some cases to yield 25 per cent less pulp than the

same kind of wood pulped when green. Even where wood was stored for a period of only one year pulp yields were one-seventh less than from the same kind of wood pulped when green. Likewise many cases were recorded where the actual cellulose content of pulp was reduced 5 to 10 per cent by storage under conditions favorable for decay. From these studies it was estimated that the total annual loss on mechanical pulp from decay while in storage is equivalent to approximately 200,000 cords and that the loss of pulp wood in storage is 400,000 cords. The paper made from infected pulp was unsatisfactory in appearance and had half or less than half the bursting and tensile strength shown by paper from sound pulp. Storage losses from decay in both cases are due to improper methods and are, therefore, preventable in large part. Pulp-wood loss may be largely eliminated by keeping wood yards free from infected wood and bark, and by using the wood in rotation so that none is allowed to remain in the yard over a year. Losses of stored pulp from decay may be prevented by the use of preservatives.

A further and very large loss occurs in the manufacture of chemical pulp, where on the average only approximately 45 per cent of the original weight of the wood is secured in pulp. The remainder is lost in the cooking liquors. Much time and money have been spent in research designed to eliminate these losses. Some hopeful results have been secured. For example, by proper cooking operations and methods of control, as demonstrated by both laboratory and mill tests, it is possible to increase the output of sulphite pulp from the same amount of wood by 10 per cent. This can be accomplished through minor modifications of the sulphite process now in general use. Any possible increase in pulp yield will obviously reduce correspondingly the amount of wood required for a specified volume of pulp or paper.

#### MODIFIED PULPING PROCESSES AND WIDER USE OF SPECIES.

The number of species which have been regarded as suitable for pulp making has gradually increased, under pressure of high prices because of timber shortage, and as a result of scientific investigations into the pulp-making properties of different woods and into the pulping processes. A new or modified pulping process which would enable pulp from such woods as beech, birch, maple, and aspen to compete with mechanical pulp would revolutionize the situation in northern New England and would greatly relieve the crisis even in New York. It would go a long way at least toward saving the present newsprint industry in these and other States, by affording time to get greatly increased timber growth under way. A process which increased the number of suitable species for sulphite or mechanical pulp, in particular, would be of great value in the solution of our entire future pulp-supply problem.

A series of investigations covering the pulp processes and the suitability of American woods for pulp has been under way in the Forest Service for a good many years. Preliminary results in one of these investigations justify comment. The wood in this experiment is chipped in the normal manner for chemical pulp; the chips are slightly but uniformly softened by chemical treatment and are then mechanically disintegrated. The high yields of 75 or 80 per cent of the original weight of the wood, the low cost of the chemical treatment, and the low power requirements indicate the possibility, in some of the results very recently obtained with hardwoods and pines, that a very satisfactory pulp can be made at a total cost comparable with mechanical pulp.

Spruce typifies the rigid requirements of the mechanical process, but the successful completion of this investigation would permit the substitution in mechanical pulp and hence in newsprint of woods of lower qualities which are now considered valueless for this purpose. The newsprint mills which experience difficulty in securing spruce and fir pulp wood might be able to turn to the local

domestic hardwoods at least during the stringent period of readjustment while growth of the softwood forests is being brought to a maximum. The greater the spruce shortage the greater will be the incentive to turn to this process or to develop one which would accomplish the same purpose. The Forest Service process promises also to make pulp from pine available as a substitute for sulphite. It might also, therefore, with its low power requirements, open up new regions of the United States, like the southern pineries, as potential areas for the development of the newsprint industry.

Whether this particular investigation works out commercially in accordance with the promise of laboratory tests or not, it at least serves as an indication of the possibilities of new or modified pulp processes. This indication and the critical need of the industry are ample justification for a large amount of research having the same objective. Some such development may well be the chief means of offsetting any pulp-wood deficit to our present industry until increased amounts can be grown.

Forest Service investigations have further shown the possibility of substituting bleached sulphate pulp made from the pines for bleached sulphite pulp made from spruce. The process is now in commercial use and more general use is possible. Unbleached sulphate pulp could replace much of the unbleached sulphite pulp now used in wrapping papers and boards. Potentially over 1 million cords of spruce could be released by such replacements.

For obvious reasons it is impossible to give a concrete sum total of how much this varied group of essential supplementary measures might at any future time decrease the demand on the forest for pulp wood under present manufacturing requirements, or how much additional pulp wood they might supply. But it is clear that in time the total could easily reach several million cords a year. In that case with forest management as a foundation it will easily be possible to supply from domestic materials all the future paper requirements of the United States.

## CONCLUSION.

### OUTSTANDING FINDINGS.

The outstanding findings of this inquiry into the pulp and paper situation are that:

The question of adequate present and future pulp-wood supplies is an important phase of the national timber supply problem, which is one of the most important problems now demanding solution in the United States.

There are outstanding reasons for creating a permanent domestic pulp and paper industry which can meet our entire needs, founded on home-grown timber. In the long run this will insure cheaper products to the ultimate consumer than can be obtained from foreign countries. The high productive capacity of our forest soils, and abundant supplies of other materials than wood essential in pulp and paper manufacture, should make cheaper products entirely feasible.

American paper requirements have nearly quadrupled since 1899 and now exceed 8 million tons a year. They constituted 56 per cent of the world's paper consumption in 1920. Our per capita consumption is double that of any other country.

The enormous growth of paper production and consumption during the past half century has been based upon wood, of which the amount now used exceeds several times that of all other materials together. The paper now consumed in the United States requires 9,148,000 cords of wood. All available information indicates that the supremacy of wood as the chief pulp material will continue.

American forests now supply only 49 per cent of the pulp wood required in our paper consumption, whereas as recently as 1899 they supplied 83 per cent. The increase in imports since 1910 has been almost entirely in pulp and paper.

Pulp-wood imports, although of great importance, now constitute only 19 per cent of the pulp wood consumed in American mills and only 11 per cent of that required for all the paper we consume. Paper and pulp imports constitute an equivalent of 42 per cent of the pulp wood needed for our entire paper requirements. About half of the pulp-wood imports are used for sulphite, three-tenths for mechanical, and the remainder for soda pulps. Newsprint, book, and wrapping papers absorb one-third, one-fourth, and one-eighth, respectively.

American forests supply less than half of the pulp wood needed for all the sulphite, mechanical, and sulphate pulp we use, but four-fifths of that needed for soda pulp. Of what is needed for newsprint paper they furnish only one-third, of that for wrapping paper two-thirds, and of that for boards and book paper slightly more than half.

Canada furnishes the pulp wood for 37 per cent of our entire paper requirements, and about equally in the form of pulp wood, pulp, and paper. Thirty-seven per cent of our entire newsprint requirements are imported from Canada as paper—more than the amount of newsprint manufactured from domestic wood. Countries other than Canada supply 17 per cent of the pulp wood needed to meet our entire paper requirements, but four-fifths of this material is imported in pulp form.

Seventy-eight per cent of the pulp wood now required consists of spruce, fir, and hemlock for sulphite and mechanical pulp, 14 per cent is pine for sulphate pulp, and the remainder is hardwoods for soda pulp. In part out of this concentration in requirements has come a concentration of the pulp and paper industry in the spruce, fir, and hemlock forests of the Middle Atlantic, New England, and Lake States. The inability of the forests of these regions to meet the demands of the pulp mills has led to imports of Canadian pulp wood, 85 per cent spruce and the remainder aspen. The Middle Atlantic States use 73 per cent of the total imports and New York alone uses 57 per cent; 21 per cent is used in New England; and the rest goes to the Lake States.

The forests of practically every region in the United States are being cut much more rapidly than they are being replaced by growth, and in most regions the original timber supplies have been greatly reduced. The regions from which pulp-wood supplies are now being chiefly secured fall within the latter class. This situation is the background of the problem of increasing the domestic pulp wood cut sufficiently to meet our requirements.

### THE PROBLEM.

The most urgent phase of the pulp and paper problem of the immediate future is to secure annually an additional 870,000 cords of spruce, hemlock, and balsam, and 180,000 cords of aspen pulp wood from our own forests, to offset pulp-wood imports. Purely economic causes make this problem urgent, regardless of any other considerations or possible developments. Closely related to the pulp-wood import problem, and only a little less urgent, is the growing shortage of pulp timber in nearly all of the Middle Atlantic, New England, and Lake States, which in itself must be faced and met in the near future. The distribution of pulp-wood imports chiefly to the Middle Atlantic States, particularly New York, and in lesser amounts to New England and the Lake States, is in itself an indication of the present shortage of local timber supplies.

An important but less urgent phase of the problem is to secure from American forests the pulp wood required to offset present pulp and paper imports. Including the amounts indicated in the preceding paragraph, this would require a total

increase in the spruce, fir-hemlock cut of about 3,916,000 cords annually, in the pine-pulp-wood cut of 773,000 cords, and in the cut of various hardwoods of 196,000 cords.

The third phase of the problem is to meet increasing future paper requirements from our own forests if possible. This, based upon the increase in requirements of the past decade or two, would necessitate a further increase in the spruce-fir-hemlock pulp-wood cut of 237,000 cords a year, in the pine cut of 110,000, and in the hardwood cut of 23,000 cords. Upon the basis of possible paper consumption of  $13\frac{1}{2}$  million tons by approximately 1950, there would be required at that time, under present manufacturing practices, nearly 12 million cords a year of spruce, fir, and hemlock pulp wood, 2 million cords of pine, and a little over 1 million cords of hardwood, or a total of about 15 million cords.

## THE SOLUTION.

### ESSENTIAL SUPPLEMENTARY MEASURES.

One possibility of making less difficult the solution of the three phases of the general pulp-wood supply problem is through new or modified pulping processes to increase the number of species available for pulp, and particularly for sulphite and mechanical pulp: If such an increase can include species which still remain in comparative abundance in the Middle Atlantic, New England, and Lake States, it will be of the first importance in relieving the present crisis.

Some relief can be secured in the spruce-fir-hemlock problem by shifting sulphate-pulp production more largely or altogether to pine or larch. Bleached sulphate pulp can also be substituted to a much greater extent for bleached sulphite pulp in book and similar papers, with corresponding reduction in spruce, fir, and hemlock requirements. Similarly, unbleached sulphate can be substituted for the sulphite in boards and wrapping paper.

It should also be possible to reduce the pulping waste in the chemical processes, where now in general only about 45 per cent of the original weight of the wood appears as pulp, and to reduce present pulp-wood and pulp losses from decay. The reuse of waste paper has grown to 29 per cent of our total paper consumption; but, if need be, it can be made to furnish to new paper much more than its present contribution of 1,850,000 tons a year.

The use of woods and sawmill waste in pulp and paper making has actually decreased during the past 15 years, despite rapidly increasing pulp-wood prices. About 20 million cords a year of the sawmill waste in species suitable for pulp can not be saved in lumber manufacture. Even with a great reduction in lumber cut and large allowance for the mills from which waste can not be secured, anything approaching the Swedish plan of integrated lumber and pulp industries would permit a vast increase in the utilization of waste over our 1922 total of less than 90,000 cords. Ultimately, with such an organization of industries and utilization as in Sweden, we could nearly double our 15 million cord pulp-wood objective without reducing saw-timber production.

### GROWING PULP WOOD THE FUNDAMENTAL SOLUTION.

All of these measures have a distinct and important place in the solution of our pulp and paper problem, and full advantage must be taken of them. Through some of them immediate results can possibly be secured to relieve critical situations. The main reliance in ultimately and fully meeting our pulp-wood requirements must, however, be placed upon the growing of timber. The possible margin of growth on our present area of forest land, under intensive forest management, over the present drain, would ultimately amount to about 12 million cords of the pulp species. To this could be added the part of about 11 million

cords of pulp species, now lost annually by fire and disease, which it is possible to save under better protection. To both could be added also 2 million cords annually from Alaska. Out of this total could be met the  $10\frac{1}{2}$  million cord difference between the present cut from our forests and an ultimate cut of 15 million cords of pulp wood, and leave a substantial difference for increased use of other wood products. The chief difficulty would arise out of a continued concentration of requirements on the spruces, firs, and hemlocks.

In some regions all of the growth on the types now supporting pulp species would be required to maintain an industry of the size of that already in existence. In others there would be a large leeway between pulp requirements and the total possible growth, so that intensive forestry on smaller areas would meet pulp-wood demands.

#### THE SOLUTION OF THE IMMEDIATE SPRUCE-FIR-HEMLOCK PROBLEM.

Unfortunately the timber supplies of New York and Pennsylvania are now so greatly reduced, in relation to demands, and provisions for their replacement by growing new supplies are still so far short of ultimate possibilities, that a curtailment of pulp production seems to be the only outlook if present pulping processes are continued. How rapid the curtailment will be, and how far it will go, depends primarily upon how soon forest management is applied, with what degree of intensity, and on what part of the area of the entire spruce-fir type. Increased cutting of pulp timber in the immediate future would merely hasten and aggravate later curtailment. While taking full advantage of the supplementary measures already outlined, the main effort in the solution of the problem in the Middle Atlantic States must therefore be to increase timber growth.

The outlook of the immediate future in New England is similar, but less critical because of the larger timber supplies in relation to plant requirements and the smaller pulp-wood imports. New Hampshire, of the three spruce States, is in the worst situation, and Vermont in the best. Vermont might succeed in supplying its own mills, but will probably be called upon increasingly to assist New Hampshire and New York. Drastic curtailment is the only outlook for New Hampshire so far as its own supplies are concerned, and reliance upon Maine and Vermont serves only to aggravate the difficulties of these States. Full advantage must be taken of supplementary measures; but the main solution in New England, as in the Middle Atlantic States, lies in the promptness, extent, and intensity of forest management on the entire spruce-fir type.

Michigan's spruce and hemlock supplies are chiefly available for Wisconsin. Wisconsin, with only limited resources of its own, draws its pulp wood largely from Michigan and Minnesota. Minnesota, with anything but a favorable spruce outlook, is trying to eliminate the competition of Wisconsin mills. Eliminating new processes, the only way in which the pulp industry can hold its own in the near future is through increased use of hemlock in competition with the sawmills, and through the possibility, already beginning in fact, of using jack pine. Both of these species are more suitable for sulphite than for mechanical pulp. Both, without intensive forest management, and possibly hemlock in any case, will be purely temporary expedients. Immediate enlargement of the pulp-wood cut or of the manufacturing industry is out of the question without corresponding curtailment later.

Under present pulping processes, therefore, new regions alone, with ample stocks of virgin timber, offer the only hope of making up in the near future either our 870,000 cords of spruce-pulp wood imports or the sum total of our dependence for spruce, fir, and hemlock pulp wood, equivalent to 3,916,000 cords. Half of the latter can be wiped out by a new industry in Alaska; three-fourths can be secured from the forests of Washington, Oregon, and California; one-fourth can

be secured from the Rocky Mountain forests in Montana and Idaho. New and enlarged regional industries should avoid the mistakes shown by past experience and develop upon a conception of permanent operation rather than for a restricted period. Only the growing of new crops of timber to replace present supplies can afford a basis for permanent plant operation.

#### THE SOLUTION OF THE FUTURE SPRUCE-FIR-HEMLOCK PROBLEM.

On the basis of present utilization, 78 per cent, or nearly 12 million cords of a future 15 million-cord pulp-wood objective, must consist of the spruces, true firs, and hemlocks. The possible cut from Alaska, the Pacific coast, and the northern Rocky Mountain States, including the present pulp-wood cut, is placed at about  $6\frac{1}{2}$  million cords annually. Allowance is made for use by other industries. This is conditional upon intensive forest management on all cut-over lands, or at least on restricted areas devoted to pulp-wood production.

Potential growth on the spruce-fir lands of the Middle Atlantic, New England, and Lake States combined can ultimately, under similar methods, exceed 6 million cords. The use of spruce for other purposes than pulp wood might perhaps be offset by the utilization of more or less jack pine, and possibly also hemlock, for sulphite pulp, and by the further possibility of cutting spruce and hemlock in the southern Appalachians. The total for the East and West would barely meet a 12-million-cord requirement, and the eastern contribution would not be available until long after 1950.

#### THE SOLUTION OF THE PINE AND HARDWOOD PROBLEMS.

Soda-pulp-wood imports of 180,000 cords and the total dependence of 196,000 cords could, if necessary, be offset in the immediate future by increasing the cut of the aspen, beech, birch, and maple forests in the New England and Middle Atlantic States. Probably the entire volume could be secured in either the Lake or the Central or the Southern States. Together these groups of States could in the immediate future, and permanently under forest management, supply requirements up to an objective of a little more than 1 million cords out of the total of 15 million, and a great deal more, if necessary. Only a relatively small part of the total area of forest land in these regions would, in fact, be necessary under forest management to meet all future requirements for soda pulp.

Similarly, the solution of the sulphate-pulp-wood problem is relatively easy. The 2,000-cord pulp-wood import is insignificant. The entire dependence of 773,000 cords could be made up altogether and the annual increase absorbed for years to come under forest management in the South alone, but the Pacific Coast, Rocky Mountain, and Lake States can also be drawn upon. Here again a relatively small part of the total forest area could under forest management produce the entire sulphate-pulp-wood requirements.

#### THE SHARE OF THE PUBLIC AND OF THE INDUSTRY IN THE SOLUTION.

Public interest in the pulp and paper problem carries public responsibility to aid in its solution. The supplies of pulp wood, lumber, and other forest products and the profitable utilization of our forest land constitute merely two phases of one of our most important national problems. The public is interested in securing permanent as contrasted with temporary industries. It is interested also in securing ample future supplies of paper at reasonable prices.

The public must redeem its responsibility by enlarging the area of publicly owned forest lands and devoting such lands in part to the growing of pulp wood.

In cooperation with private owners it must extend and improve protection against fire, insects, and disease. It must solve the question of forest taxation, which in its present form helps to discourage efforts by private owners to grow their own timber supplies. It must encourage the development of satisfactory forms of timber insurance. It must aid in forest-products research into pulp woods and pulping processes. To supplement present knowledge, it must, in cooperation with the pulp and paper industry, extend and enlarge the research of forest experiment stations in methods of reforestation, timber growing, and protection. It must also secure fuller data on the adjustment of needs and supplies. Although the general information available amply justifies action along the lines suggested, much more accurate and detailed data on timber supplies, growth, requirements, and available forest lands are essential for thoroughly satisfactory plans from the standpoint of either the pulp and paper industry or the public. For such data reliance can be placed only upon a timber survey, and in making this the public and the industry must cooperate.

The interest of the industry in planning and providing for itself ample supplies of raw materials to meet its own future requirements is still more immediate and direct than that of the public and carries corresponding responsibility for the solution of the pulp and paper problem.

The responsibility of the industry extends to cooperation in the lines indicated—forest protection, forest-products investigations, research at forest experiment stations, and a thoroughgoing timber survey. It includes systematic and widespread efforts to apply the results of research as rapidly as they become available. Further than all of these, the pulp and paper industry should, to safeguard its own interest, assume the leadership in timber growing on its own forest lands and those upon which it is dependent for pulp-wood supplies. The alternative of scrapping pulp and paper plants or diverting them to other and less essential products affords no real choice.

## APPENDIX.

TABLE 1.—*Paper consumption of the United States and the wood pulp and pulp wood required in its manufacture.*

[Quantities in tons of 2,000 pounds and cords of 128 cubic feet.]

Year.	Paper.	Wood pulp.	Pulp wood.	Year.	Paper.	Wood pulp.	Pulp wood.
	<i>Tons.</i>	<i>Tons.</i>	<i>Cords.</i>		<i>Tons.</i>	<i>Tons.</i>	<i>Cords.</i>

<sup>1</sup> Under present forest management, new tree growth is largely volunteer. By "crude forestry, 1950," is meant the annual growth that may be expected by 1950 if such crude measures as fire protection and seed trees where needed are adopted immediately. By "crude forestry, ultimately" is meant the utmost growth that can finally be secured by these crude measures. By "intensive forestry," is meant an intensive management of forests as crops, comparable to forestry as practiced in some of the European countries.

<sup>2</sup> It is estimated by H. B. Peirson, forest entomologist of Maine, that the growth rate of the spruce-fir in that State is retarded about one-third as the result of the damage by the spruce bud worm. On this basis, the total cubic-foot and board-foot growth for New England would be reduced about 5 million and 4 million feet, respectively.

Table 11. Source of the wood pulp required in the paper consumption in the United States.....	76
Table 12. Source of paper consumed in the United States.....	76
Table 13. Wood pulp required for the paper consumed in the United States.....	76
Table 14. Pulp wood required for the paper consumed in the United States.....	77
Table 15. Source of the pulp wood used to meet the soda wood-pulp requirements of the United States.....	77
Table 16. Source of the soda wood pulp utilized by the United States.....	78
Table 17. Source of the pulp wood used to meet the sulphate wood-pulp requirements of the United States.....	78
Table 18. Source of the sulphate wood pulp utilized by the United States.....	78
Table 19. Source of the pulp wood used to meet the sulphite wood-pulp requirements of the United States.....	79
Table 20. Source of the sulphite wood pulp utilized by the United States.....	79
Table 21. Source of the pulp wood used to meet the mechanical wood-pulp requirements of the United States.....	79
Table 22. Source of the mechanical wood pulp utilized by the United States.....	80
Table 23. Source of the wood pulp used in the book paper consumed in the United States.....	80
Table 24. Source of the wood pulp used in the paper board consumed in the United States.....	80
Table 25. Source of the wrapping paper consumed in the United States.....	81
Table 26. Source of the newsprint paper consumed in the United States.....	82
Table 27. Dependence of the United States on countries other than Canada for wood pulp and paper.....	83
Table 28. United States imports from Canada of pulp wood, wood pulp, and paper.....	84
Table 29. Rate of increase of imports to meet the United States paper consumption, 1899-1922.....	84
Table 30. Wood-pulp imports into the United States.....	85
Table 31. Sulphate-pulp imports into the United States.....	85
Table 32. Sulphite-pulp imports into the United States.....	85
Table 33. Mechanical-pulp imports into the United States.....	86
Table 34. Pulp-wood and paper imports of the United States.....	86
Table 35. Average annual consumption of imported spruce and aspen, by States, 1918-1922.....	87
Table 36. Book-paper imports of the United States.....	87
Table 37. Wrapping-paper imports of the United States.....	87
Table 38. Newsprint-paper imports of the United States.....	87
Table 39. Wood-pulp and paper exports from the United States.....	88
Table 40. Imports of wood pulp and specified grades of paper into the United States, by principal countries, for 1922.....	89

	Page.
Table 41. Pulp-wood prices in the United States.....	89
Table 42. Pulp-wood, wood-pulp, and newsprint production and exports of Canada.....	89
Table 43. Wood-pulp production of Canada.....	90
Table 44. Quantity of standing timber in the United States, by regions.....	90
Table 45. Total stand of timber of principal kinds suitable for pulp, by regions.....	91
Table 46. Forest areas, by types and regions.....	92
Table 47. Present and possible annual growth of forest types of the United States, by State groups.....	92
Table 48. Timber removed annually from the forests of the United States.....	94
Table 49. <i>Middle Atlantic States</i> .—Stand of pulp species and growth, by forest types.....	95
Table 50. <i>New York</i> .—Stand of pulp species, lumber cut, and pulp-wood consumption.....	95
Table 51. <i>Pennsylvania</i> .—Stand of pulp species, lumber cut, and pulp- wood consumption.....	95
Table 52. <i>New England States</i> .—Stand of pulp species and growth, by forest types.....	95
Table 53. <i>Maine</i> .—Stand of pulp species, lumber cut, and pulp-wood consumption.....	96
Table 54. <i>New Hampshire</i> .—Stand of pulp species, lumber cut, and pulp-wood consumption.....	96
Table 55. <i>Vermont</i> .—Stand of pulp species, lumber cut, and pulp-wood consumption.....	96
Table 56. <i>Lake States</i> .—Stand of pulp species and growth, by forest types.....	96
Table 57. <i>Michigan</i> .—Stand of pulp species, lumber cut, and pulp-wood consumption.....	97
Table 58. <i>Wisconsin</i> .—Stand of pulp species, lumber cut, and pulp-wood consumption.....	97
Table 59. <i>Minnesota</i> .—Stand of pulp species, lumber cut, and pulp-wood consumption.....	97
Table 60. <i>Pacific Coast States</i> .—Stand of pulp species and growth, by forest types.....	97
Table 61. <i>Southern States</i> .—Stand of pulp species and growth, by forest types.....	98
Table 62. <i>Rocky Mountain States</i> .—Stand of pulp species and growth, by forest types.....	98
Table 63. <i>Central States</i> .—Stand of pulp species and growth, by forest types.....	98
